The programme of this section dealt largely with problems relating to administration and curriculum. The question of securing State support for land-grant colleges was presented by President Fellows and discussed by Dean Henry and President Stimson. A better appreciation by the public of the work and needs of the institutions was considered the chief desideratum. Among the agencies which had been found helpful in securing this by bringing the public into closer touch were mentioned the better-farming railway specials, the running of excursions to the colleges, summer schools, short winter courses, and the enlistment of the farmers' organizations.

The Selection and Retention of an Efficient Teaching Force was discussed by President W. E. Stone and others. A considerable divergence of opinion developed as to the most satisfactory means

of securing men, some preference being expressed for their training and advancement at a single institution, while others favored securing the best men wherever found. Transfers of instructors from one institution to another during the college year were deprecated, and the necessity of maintaining among instructors a feeling of permanency of tenure during good service was emphasized. A certain flexibility of salaries and the treating of each case individually was also recommended as beneficial in many instances. It was believed that much can often be accomplished even with low salaries by arranging congenial work and by providing adequate funds for the maintenance of the departments.

Special interest in this section centered around the question of the preparation of instructors for teaching the elements of agriculture and the mechanic arts as authorized by the Nelson amendment. President White opened the discussion, calling attention to the rapid development of agricultural education in the secondary and primary schools and the great dearth of competent teachers. The feasibility of preparing such instructors in the land-grant colleges was considered, and also the relations of these institutions to the normal schools in such work. President Bryan, of Washington, described the department of education in the Washington State College. He emphasized the necessity of supplementing instruction in the purely agricultural phases by the study of general pedagogic methods, and regretted that so little interest in agricultural education thus far had been taken by trained educators. President Butterfield outlined the scope and purpose of the department of agricultural education recently established in the Massachusetts Agricultural College, and Prof. C. B. Waldron, of North Dakota, described the three years' teachers' course in that State. Doctor True pointed out certain fundamental distinctions in the attitude of the land-grant colleges and the normal schools toward agricultural education. In his opinion, the fullest development was to come through a serious cooperation of all available agencies, including the colleges, the normal schools, the Department of Agriculture, and the Bureau of Education. A short history of an attempt to introduce elementary agriculture into the rural schools in Scotland and its failure by reason of the withdrawal of the government grants was presented by Professor Wallace.

A paper on Extension Work in Agriculture was presented by Prof. F. H. Rankin, of Illinois, who described salient features of that work, its significance, and profitable lines of development.

The Short Practical Course, Its Value and Importance, was discussed by Dean Curtiss. A letter of inquiry showed that such courses were conducted last winter in 34 of the 39 colleges reporting, with a total enrollment of 7,776 persons, an average of 228 to each State.

Opinions as to the value of the work were highly favorable, though its limitations as an educational agency are generally recognized. As a means of strengthening the institutions in clientage and public confidence their existence seems to have been fully justified. The present is apparently a period of transition, with a tendency to reduce the amount of the more extended short-course work and to place greater emphasis on that of college grade—a condition likely to be accentuated by the development of agricultural instruction in secondary schools. In the speaker's opinion, still further abbreviation of the short courses was to be expected and their eventual classification with extension work.

In the discussion which followed the consensus of opinion seemed to be that the secondary schools would not supplant the short courses, but would modify their character to a marked degree and make their chief function that of centers of specialized instruction.

SECTION ON EXPERIMENT STATION WORK.

The general subject of the papers presented before this section was Present Day Problems in Plant Pathology. Under this heading Prof. M. V. Slingerland considered The More Urgent Problems in Insect Control, the problems being classified as national and local. In the first class were placed such introduced insects as the cotton-boll weevil and the gipsy moth, which menace great industries or the general agriculture of whole sections, and such questions as a national quarantine against insects and uniform nursery inspection laws, the solution of which must depend largely on national action. Of problems of a more local nature the San José scale, codling moth, peach borer, plum curculio, woolly aphis, and apple maggot were reported as especially needing consideration, together with a general study of insects living under ground, forest and greenhouse insects, plant lice, and many others. To gain control of these, exhaustive studies of climatic and other complex factors are necessary. Owing to the vastness of the field in this country, and the manifold demands made upon the entomologist for various kinds of work, it was stated that few, if any, of the insect problems had been worked out to the entire satisfaction of entomologists and agriculturists.

In a paper on Progress in the Control of Fungus and Bacterial Plant Diseases, Prof. F. C. Stewart expressed the opinion that more progress in the actual control of fungus diseases had been achieved during the past twenty-five years than in all previous time. This is due largely to the discovery and application of fungicides. A certain amount of assistance is probable from the selection of disease-resistant varieties, although it was believed that the importance of this factor may have been greatly overestimated. Much has still to be done on

the causes of the diseases, in the tracing of the life histories of many of the fungi, and especially in devising effective means of control. It was suggested that ignorance of the methods of practical agriculture has been responsible for many impracticable recommendations by plant pathologists, coupled with a disinclination to make field experiments. The speaker advocated thorough testing of methods of treatment on a commercial scale during a series of years as the safest and most effective method of procedure. Because of the complexity of many problems, cooperative investigations with the economic entomologist, the bacteriologist, the agriculturist, the horticulturist, or the chemist were considered as often very essential.

In a discussion of this paper the need for cooperation by investigators in different States in the study of those diseases which appear only at intervals in a given region, such as potato blight and rot and the downy mildew, was suggested. A similar opportunity was pointed out in connection with the introduction of resistant strains and varieties from other localities.

The Relation of Cultural Methods to Plant Diseases was presented in a paper by Dr. G. E. Stone.

The topic for general discussion was The Duplication of Work in Agricultural Investigation, led by papers by Director H. T. French on the duplication among stations, and by Prof. H. Garman on the duplication between the stations and the U. S. Department of Agriculture.

The special topic decided on for the next meeting was Milk Production, including Sanitation; and the subject for general discussion, The Relation of the Experiment Station to Instruction Work, with Special Reference to Its Popular Phases.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

The use of corrosive sublimate for the preservation of samples of milk for analysis, P. GRÉLOR (*Jour. Pharm. et Chim.*, 6. ser., 25 (1907), No. 9, pp. 423-428).—Of the various antiseptics tested for the preservation of milk samples, mercuric chlorid has given the best results in the author's experience. The bichlorid is rendered more soluble by the addition of one-fourth of its weight of ammonium chlorid. A tablet suitable for preserving a 250 cc. sample of milk would contain 0.05 gm. of mercuric chlorid and 0.0125 of ammonium chlorid, and would lower the freezing point 0.006° C. The use of such tablets would avoid, according to the author, the many inconveniences of potassium bichromate.

The determination of fat in cream, M. SIEGFELD (*Molk. Ztg.*, 21 (1907), No. 13, pp. 331, 332).—The Adams method and the Gerber acid method were compared. In the acid method the cream was weighed but not diluted with water. The averages of duplicate determinations by both methods agreed closely.

Determination of fat in condensed milk, S. HALS and O. B. KLYKKEN (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 13 (1907), No. 6, pp. 338-345).—Comparative determinations were made by the methods of Gottlieb, Adams, Gerber, and Schmid. The highest results were obtained by the Gerber method. In general, the results by the Gottlieb, Adams, and Gerber methods were unaffected by the addition of sugar. This was not true, however, of the Gerber method when the fat content of the milk was very low.

The refraction of fats and fatty acids, R. K. DOXS (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 13 (1907), No. 5, pp. 257-261).—The difference between the index of refraction of butter fat and those of the insoluble fatty acids at a temperature of 40° C. is from 11.2 to 11.5. In the case of coconut oil the difference is 16.9, which is sufficiently great to permit of the detection by this means of the adulteration of butter with coconut oil.

The refractometric examination of milk and cream and its applicability in food control, E. BAIER and P. NEUMANN (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 13 (1907), No. 7, pp. 369-384, figs. 4).—The milk is treated with acetic acid and alkaline-copper-carbonate solution and centrifuged. Determination is made of the index of refraction of the ether solution of the fat. A table is given which shows the percentages of fat corresponding to the different degrees of refraction. Cream is diluted with 9 parts of skim milk of which the fat content has been previously determined. Comparative determinations by this method and the Adams and Gottlieb methods are reported. The variations were not marked.

Estimation of lactose and butter fat in milk chocolate, W. L. DUBOIS (*Jour. Amer. Chem. Soc.*, 29 (1907), No. 4, pp. 556-561).—The author's results were summarized as follows:

"In order to prove a milk chocolate true to name it is necessary to establish the presence of desiccated milk. This may be done by estimation of lactose and butter fat.

"Heating a solution of lactose to 86° C. decreases the polarimetric reading by an amount which may be corrected by multiplying by 1.11.

"Sucrose and lactose may be determined in the same solution by polarizing the sucrose in the usual way and lactose at 86°, after the inversion of the sucrose.

"These sugars may be rapidly and accurately determined in sweet and milk chocolates by the optical method described.

"Butter fat in milk chocolate may be approximately estimated from the Reichert-Meissl number of the fat extracted therefrom."

The inversion of sucrose by acid mercuric nitrate, C. B. COCHRAN (*Jour. Amer. Chem. Soc.*, 29 (1907), No. 4, pp. 555, 556).—The author gives the results of numerous experiments with acid mercuric nitrate solution as an inverting agent for sucrose. The method is considered capable of giving reliable results and is commended on the grounds of simplicity and ease of execution. As the acid mercuric nitrate does not affect the polarization of lactose, it may be employed with safety in the analysis of sweetened condensed milk.

The unification of reducing-sugar methods, P. H. WALKER (*Jour. Amer. Chem. Soc.*, 29 (1907), No. 4, pp. 541-554).—This is an extension of the table of Munson and Walker, the two tables together giving the necessary data for all of the more common reducing sugars.

Improvements in the autoclave method of estimating crude fiber, W. BREMER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 13 (1907), No. 8, pp. 488-490, fig. 1).—In the author's opinion, materials may be more conveniently treated with glycerin-sulphuric acid in small porcelain cups than in porcelain evaporating dishes. Where the cups are used, less time is required and the results are fully as accurate. A metal stand for holding a number of the cups is described.

The amount of cellulose, lignin, and cutin in pepper and cocoa, H. FINCKE (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 13 (1907), No. 5, pp. 265, 266).—Determinations of pure cellulose, lignin, and cutin showed that not half of the so-called crude fiber of the substances examined consisted of cellulose. The determination of these constituents of crude fiber, in the author's opinion, does not furnish a better means for judging of quality than do values for total crude fiber.

[Laboratory apparatus] (*Delaware Sta. Rpt.* 1903, pp. 113-116, fig. 1).—Illustrated descriptions are given of an ammonia condenser for use in the Kjeldahl method and of a form of Bunsen burner with metallic connections for use in batteries or clusters.

METEOROLOGY—WATER.

Monthly Weather Review (*Mo. Weather Rev.*, 34 (1906), No. 13, pp. XVI+609-628, charts 6).—This number contains a table of contents, list of corrections and additions, and an index of volume 34; a report of the Chief of the Weather Bureau for the fiscal year ended June 30, 1906; a report of the Forecast Division; and a summary of observations on pressure, temperature, precipitation, humidity, cloudiness, and other meteorological phenomena.

"The normal annual distribution of atmospheric pressure shows the existence of two well-defined high areas—one over the Ohio Valley, east Gulf, and South Atlantic States, and extending eastward over the Atlantic, with the crest, 30.10 in. or above, east of the Bermudas; while the second high area covers the Pacific between the Hawaiian Islands and the coast of Oregon and northern California, extending eastward into northern California and central Oregon.

"During 1906 high pressure covered the greater part of all districts east of the Mississippi Valley, except the Florida Peninsula and New England, and extended in a narrow strip westward over the lower Missouri Valley into the central Rocky Mountain and plateau districts.

"Pressure averaged unusually high over the eastern slope of the Rocky Mountains and in the upper lake region and northward over the Province of Ontario, where the normal was exceeded from 0.05 to 0.07 in.

"In a narrow strip along the coast of southern California and over the greater part of northern California and the western portions of Oregon and Washington, also over the Florida Peninsula, the pressure averaged slightly below normal; otherwise over all districts of the United States and Canada the average for the year was above the normal.

"The year was one of unusual warmth over nearly all districts. Along the entire northern border from the lower lakes westward to the Pacific the annual means averaged 2° or more above the normal, and across the border in Manitoba and surrounding districts the average for the year exceeded the normal from 3° to more than 5° .

"In the southern portions of Georgia and Alabama and over the Florida Peninsula the temperature averaged slightly below normal, also over western Texas and the greater part of New Mexico, Arizona, and Utah. . . .

"Maximum temperatures of 100° or higher were recorded in the upper Missouri Valley, at scattered points in the Gulf States, in central and western Texas, over the southern portions of New Mexico and Arizona, and the central portions of California, Oregon, and Washington.

"Minimum temperatures of 30° below zero or lower were confined to portions of northern New England, northern Minnesota, North Dakota, and to the elevated stations of the central Rocky Mountain district. . . .

"The total precipitation for 1906 was below the normal along the Atlantic coast from Virginia to central Florida, and over the Gulf coast from western Florida to Texas. The deficiency on the immediate coast line was very marked, ranging from more than 12 in. at Hatteras to nearly 20 in. at New Orleans. Precipitation was also deficient over New England, New York, Pennsylvania, the Lake region, central Mississippi and lower Missouri valleys, and over the north Pacific coast districts.

"In marked contrast with the deficiency along the Atlantic and Gulf coasts, the amount of fall over the Appalachian Mountain region from Pennsylvania southward to the central parts of the east Gulf States, and in a narrow strip westward over Alabama, northern Mississippi, central Arkansas, and northern Texas, ranged from 5 to as much as 25 in. above the average.

"Precipitation was also in excess over practically all the Great Plains district from central Texas to North Dakota, over the entire Rocky Mountain and plateau districts, and the Pacific coast from central Oregon to southern California.

"The annual fall was especially heavy over central and northern Texas and the central and western portions of Oklahoma, Kansas, and Nebraska, where amounts from 10 to 12 in. above the normal were recorded.

"In the central Rocky Mountain States, northern New Mexico, Arizona, Nevada, and central and southern California, the excesses were generally large, although at isolated points the amounts were less than the average.

"The year was one with rainfall in general sufficient for all ordinary requirements, and generally well distributed through the growing season. An unusual amount of cloudy weather was the rule in nearly all districts, and the relative amount of moisture was generally in excess of the average."

Report of the meteorologist, W. H. BISHOP (*Delaware Sta. Rpt. 1903, pp. 160-166*).—A summary of the usual observations for the year 1902.

Meteorological observations, J. E. OSTRANDER and T. A. BARRY (*Massachusetts Sta. Mct. Buls. 219, 220, pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during March and April, 1907. The data are briefly discussed in general notes on the weather of each month.

Summaries of temperature, rainfall, and sunshine, E. F. LADD (*North Dakota Sta. Rpt. 1906, pt. 1, pp. 17-27*).—The temperature for each month of 1906, the rainfall for each month of that year and for each year since 1892, the monthly sunshine for each month of 1906, the daily wind velocity for each month, and the daily evaporation from the water surface for the months May to September during 1906 and 4 preceding years are given in tables and briefly discussed. The average temperature for 1906 was 47.3° F., being considerably higher than that of the previous year. The total rainfall, 17.7 in., was much lower than that of the preceding year, 30.76 in., and lower than the average for the past 15 years, 21.36 in. The total sunshine recorded for the year was 1,925.4 hours. "The total amount of water evaporated from a water surface for the five months [May to September] was 22.36 in., a monthly average of 4.472 in., and a daily average of 0.145 in. This is considerably less than for the preceding years."

Semi-arid America; its climate compared with that of South Australia, W. L. SUMMERS (*Jour. Dept. Agr. So. Aust., 10 (1907), No. 7, pp. 411-414*).—In view of the great interest which has been manifested in Australia in reports of wheat growing in semi-arid districts of the United States, especially in the Campbell system of dry farming, the author undertakes a comparison of the climatic conditions of South Australia and that part of the United States which is defined as semi-arid. The main differences between the climatic conditions of the semi-arid districts of the United States and the so-called dry districts of South Australia are summarized as follows:

South Australia.—Where our average rainfall exceeds 15 in. the district is regarded as a safe one for wheat and sheep, while our 'dry-wheat areas' would average, say, 10 to 15 in. The elevation above sea level of these dry areas is from a few hundred to nearly 2,000 ft. The winter is somewhat cold, often frosty, with lengthy intervals between appreciable falls of rain. The spring is relatively dry, and hot, drying winds while the wheat is flowering often cause serious loss. The average summer temperature is high, and frequently the shade records reach 100° F. for a week at a time. The wheat is sown at the beginning of winter, has to make its growth during relatively cold weather, and mature its grain in the hot, dry months of late spring and early summer.

America.—The rainfall of the so-called semi-arid districts appears to be from 18 to 20 in. The altitude is from 1,000 to 8,000 ft.; winter is cold, but dry. The summer is wet and war., and extended periods without rain are rare. The wheat is sown in spring and harvested within about 120 days, and during the whole of the growing period relatively high temperatures rule, though, as previously pointed out, extremely cold weather is frequently experienced. Evaporation is consequently considerably less than in South Australia, and the frequency of the summer rains, even when limited, tends to replenish the losses by evaporation.

"It will therefore be seen that the contrast between the climatic conditions of the two countries is very marked, and that results in the American States can scarcely be compared with local results. Our experience with the so-called drought-resistant wheats which have been introduced into these regions during

the past eight or ten years has been that they keep on the ground too long—that is, make but little upward growth until the warmer weather sets in, and then too often before they mature their grain they are caught with hot winds. On the other hand, except in the coldest districts, our ordinary wheats make considerable growth before the spring sets in, and thus have more prospect of maturing their grain."

The weather maps of the public weather service, GROHMANN (*Sächs. Landw. Ztschr.*, 54 (1906), No. 50, pp. 1305-1310, figs. 2).—The character and use of the weather maps issued by the German weather service are explained.

Weather predictions, JOCHIMSEN (*Landw. Wechbl. Schles. Holst.*, 57 (1907), Nos. 10, pp. 137-139; 11, pp. 149-152).—Brief explanations of weather predictions and their utilization in agriculture are given.

On purification of sewage waters, A. MUNTZ and E. LAINÉ (*Compt. Rend. Acad. Sci. [Paris]*, 144 (1907), No. 9, pp. 466-470).—Experiments with filters of peat are reported which tend to show that it is possible by proper manipulation of this material to increase enormously the purification capacity of bacterial filter beds.

Nitrification of sewage, G. REID (*Proc. Roy. Soc. [London]*, Ser. B, 79 (1907), No. B 528, pp. 58-74, figs. 2; *Jour. Roy. San. Inst.*, 28 (1907), No. 3, pp. 142-149).—This paper reports the results of observations on the influence of the depth of filters and the size of particles on the efficiency of the purification. By means of shallow trays with perforated covers placed at 1 ft. intervals in a filter bed composed of $\frac{3}{4}$ -in. particles, studies were made of the progress of nitrification in the sewage at different depths. The results show that the nitrification took place very largely in the first 12 in. of the filter, and indicate that in general the efficiency of a filter is to be increased by extending its area and by using finer particles rather than by increasing its depth.

The bacterial treatment of sewage, W. D. SCOTT-MONCRIEFF (*Surveyor*, 31 (1907), No. 790, pp. 331-333, figs. 2; *Jour. Roy. San. Inst.*, 28 (1907), No. 3, pp. 147-149, figs. 5).—Experiments similar to those recorded in the preceding article and with like results are reported.

SOILS—FERTILIZERS.

A review of the geographical and geological conditions of Alaska, A. RÜM. (*Mitl. Justus Perthes' Geogr. Anst.*, 53 (1907), No. 1, pp. 1-16, map 1).—The general geology, hydrography, and climate are briefly reviewed. A colored map based upon that of E. C. Barnard, of the U. S. Geological Survey, illustrates the main features of the present knowledge of the physical geography of Alaska.

The agricultural-bacteriological examination of soils, R. PEROTTI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis. Mat. e Nat.*, 5, ser., 16 (1907), I, No. 1, pp. 67-75).—The author briefly reviews a number of the more important reports of investigation on this subject and reports a series of studies of the growth of soil organisms in a medium consisting mainly of an extract of peat in comparison with other standard culture media.

The peat extract was prepared by boiling 100 gm. of air-dry peat over a direct flame for 2 hours with 500 cc. of water and digesting another 100 gm. for 2 hours in an autoclave at 120° with 500 cc. of water, filtering, and combining the extracts. For use as a culture medium the extract was diluted until it contained about 1 per cent of mineral matter. This solution had a slightly acid reaction. Both the acid solution and that which had been made slightly alkaline were used in the experiments reported. The growth of micro-organisms was much more rapid in the alkaline extract to which glucose had been added

than in any of the other media used. The peat extract medium seemed to be especially favorable for the isolation of the nitrogen-fixing organisms.

Investigations on capillarity, II. OLLIVIER (*Ann. Chim. et Phys.*, 8. ser., 10 (1907), *Fcb.*, pp. 229-288, figs. 17; *Mar.*, pp. 289-321, pls. 3, figs. 22).—The results of these investigations are reported under four heads as follows: (1) Formation of small drops, variations in their weight and form, (2) the influence of compressibility on the formation of drops, (3) contact of water with wet surfaces, and (4) the direct and chronophotographic study of different stages in the regular formation of drops.

On the source, amount, and importance of carbon dioxid in soils, J. STOKLASA and A. ERNEST (*Ztschr. Zuckerindus. Böhmen*, 31 (1907), No. 5, pp. 291-307).—Measurements of the carbon dioxid produced in different kinds of soils under a variety of conditions are reported, the results indicating that the two chief sources of this gas are the respiration of the roots of the higher plants and of the micro-organisms which occur in soils. From the data secured it is estimated that the roots of each wheat plant give off during each day of its period of growth an average of 0.03 gm. of carbon dioxid. It is further estimated that the micro-organisms in 1 kg. of cultivated soil respire 15 mg. of carbon dioxid in 24 hours, or 75 kg. per hectare per day for the 200 days of the year in which the temperature is 15° C. or above.

On lime concretions, E. BLANCK (*Landw. Vers. Stat.*, 65 (1907), No. 5-6, pp. 471-479; *abs. in Jour. Chem. Soc. [London]*, 92 (1907), No. 534, II, p. 295).—Studies of the chemical composition and absorptive properties of concretions found in calcareous soils are reported.

The analyses reported show the concretions to consist mainly of calcium carbonate, silica, iron oxid, and alumina, with smaller amounts of various other constituents. Fifty gm. of the fine-ground concretions were shaken up with 200 cc. of tenth-normal potassium nitrate solution containing 0.943 gm. of potash and allowed to stand 48 hours. The absorption of potash was at the rate of 0.1904 gm. per 100 gm. of material and the solution of lime at the rate of 0.1096 gm. Treated in the same way with a tenth-normal solution of ammonium chlorid the absorption of nitrogen was 0.0592 gm. per 100 gm. of material and the solution of lime 0.136 gm. When treated with hundredth-normal monocalcium phosphate solution 100 gm. of material absorbed 0.52 gm. of phosphoric acid.

A comparison of ground and unground concretions showed that the absorptive capacity for phosphoric acid was greater in case of the latter than in case of the former. These results show that the concretions may exert a marked influence upon the absorptive properties of soils.

[**The effect of**] volcanic ash on crops, W. N. SANDS (*Mo. Consular and Trade Rpts.* [U. S.] 1907, No. 318, p. 41).—A brief account is given of the decidedly injurious effect on cacao, cotton, pigeon pea, sugar cane, etc., of volcanic ash which fell on the Island of St. Vincent during the last eruption of Soufriere.

The agricultural value of the phosphoric acid of Belgian subsoils, C. SCHREIBER (*Rev. Gén. Agron.*, n. ser., 2 (1907), No. 1, pp. 1-8).—The results of a series of pot experiments with typical ferruginous, clay, and sandy subsoils from different parts of Belgium are summarized, the crops used in the experiments being oats followed by clover. The results show that, while the subsoils contained a considerable percentage (0.62) of phosphoric acid, a very small percentage of it was assimilated by plants, it being apparently in such form that it was very slowly dissolved in the soil solutions.

Availability of phosphates in relation to soil acidity, A. R. WHITSON and C. W. STODDART (*Wisconsin Sta. Rpt.* 1906, pp. 171-180, fig. 1).—Tests of the acidity and fertilizer requirements, especially for phosphoric acid, in a large

number of soils, both in the field and in the plant house, are described. The results in general indicate with reasonable certainty "that acid soils need phosphates, and it will be possible, by a careful test of a soil with litmus paper, to tell if it needs, or will need in the immediate future, a phosphate fertilizer."

The nitrogen content of soils as affected by methods of farming, A. R. WHITSON, C. W. STODDART, and A. F. MCLEOD (*Wisconsin Sta. Rpt. 1906, pp. 160-170*).—Studies of cropped and virgin soils similar to those reported by Snyder of the Minnesota Station and Ladd of the North Dakota Station are reported.

Analyses were made of samples of soil from a large number of fields, the histories of which are fairly well known, and of samples of virgin soil surrounding and adjacent to them. Summing up the results it is shown "that, in 6 out of 21 cases, the difference in amount of nitrogen in the virgin and cropped soil is not enough to account for the crops which have been removed." It is suggested that this condition is a result of fixation of nitrogen by soil bacteria.

"On the average, the determinations show that the loss by leaching and denitrification amounts to only 22.3 per cent of the amount of nitrogen removed by crops. The evidence seems to indicate that in clay loam soils of moderate fertility more than four-fifths of the nitrogen lost is removed by crops.

"It is probably true that in soils of a higher degree of fertility, and especially where large amounts of fertilizers are used on land growing late cultivated crops, there is a larger loss of nitrogen by leaching and denitrification than is noted in the above cases. Nevertheless, the entire loss of nitrogen from these fields is, on the average, 37.1 per cent of their original content, as determined by this method. This indicates clearly the limited store of nitrogen in such soils and the importance of maintaining it by the growth of clover, or other legumes, and manure."

Denitrification in cultivated soils, G. AMPOLA and S. DE GRAZIA (*Staz. Sper. Agr. Ital., 39 (1906), No. 6-7, pp. 593-609; Gaz. Chim. Ital., 36 (1906), II, No. 5-6, pp. 893-905; abs. in Chem. Zentbl., 1907, I, No. 7, pp. 655, 656*).—In continuation of previous experiments by Ampola (*E. S. R., 17, p. 17*) the authors here report a series of comparisons on volcanic soils of calcium and sodium nitrates and farm manures as regards the changes which their nitrogen undergoes in the soil and their efficiency when used singly or in combination on different crops.

It was found that the nitric nitrogen of calcium nitrate is more readily assimilated by plants than that of sodium nitrate, which is ascribed to the fact that calcium nitrate is the ultimate product of nitrification in the soil, and nitrogen in this form offers greater resistance to denitrifying organisms than that of sodium nitrate. This fact, first pointed out by Ampola in 1901, has been confirmed by recent experiments by Bellenoux (*E. S. R., 17, p. 449*).

It was also found that denitrification was less rapid in the case of well rotted manure than of fresh manure. Denitrification was apparently greater and the resultant yield of crops less in case of manure containing litter than in case of manure not containing such material. The application of straw to the soil in all cases caused a decrease in yield, and even when sodium nitrate was used with the straw the yield was but very slightly increased. The injurious effect of the straw both alone and in connection with sodium nitrate and manure is attributed in part to the increased aeration of the soil brought about by its use, which is believed to promote denitrification. The decrease in yield is attributed more especially to denitrification because the soils experimented with were such as are ordinarily benefited by aeration and are rendered more productive by the common practice of plowing under stubble or sod. It is

believed that the straw promotes denitrification by furnishing food for the denitrifying organisms in the form of pentosans. Calcium nitrate was more effective in combination with straw, manure, and like substances than sodium nitrate, being apparently more resistant to denitrification.

The yields were invariably lower when fresh manure was applied just before seeding than when applied some time before this operation. In order to obtain the best results, therefore, the manure should either be well rotted before it is applied or it should be applied some time before the seeding.

The objections noted in the case of straw were not found to hold in the case of green manures similarly used, and this is ascribed to the fact that the organic matter of the green manures is more rapidly converted into humus than that of the straw.

Comparative tests of different kinds of manure showed that the least denitrification and largest yields occurred in the case of sheep manure, the order of efficiency of other manures tested being cow manure, horse manure, cattle manure with litter, and horse manure with litter. In general, denitrification was more active with manure of horses than with that of cattle or sheep, the addition of litter in all cases increasing the rate of denitrification. The low rate of denitrification in case of manure from sheep is ascribed to the fact that with these animals the carbohydrate materials which serve as food for the denitrifying organisms are more thoroughly digested than in case of cattle or horses.

The results do not warrant the conclusion that stable manure is of questionable value, provided care is taken to use manure in a proper state of decomposition or to apply it a sufficient length of time before seeding or before application of nitrates.

Relation of soil bacteria to nitrogenous decomposition, C. HOFFMANN (*Wisconsin Sta. Rpt. 1906, pp. 120-134, fig. 1*).—The rate of decomposition as measured by the formation of ammonia and nitrates in the nitrogenous matter of blood meal, bone meal, bran, and peat was studied in culture experiments with gelatin extracts, according to Remy, of 4 distinct types of soils, namely, black marsh soil sandy in character, a heavy sticky clay, a light sandy loam, and a pure sand. The facts apparently established by the investigations are summarized as follows:

“The numbers and the character of the bacterial flora in soils are largely influenced, first, by the nature of the fertilizers applied, and second, by the character of the soils themselves.

“The number of bacteria in sand is the smallest, amounting to only about one-fifth of that found in the black marsh soil, which contained the greatest number of any of the four soils.

“The total number of bacteria which may develop in soils richly fertilized is enormous, aggregating hundreds of millions per gram.

“The degree of nitrogenous decomposition is, in a general way, directly dependent upon the total number of bacteria present.

“The progress of such decomposition is marked by numerous fluctuations which coincide, in a general way, with an increase or decrease in the number of bacteria.

“Extensive ammonification invariably occurs before nitrification becomes active. Large amounts of ammonia may be formed in soil, without interfering with the subsequent development of the nitrate-forming organisms. In soils highly fertilized, as in the foregoing experiment, appreciable amounts of ammonia are invariably present.

“As regards the degree of decomposition, the soils tested rank in the following order: black marsh, clay, sandy loam, and sand.

"When based upon their relative susceptibility to decomposition, the fertilizers used rank thus: blood meal, bran, bone meal, and peat. In other words, where immediate effects are required, blood meal and bran are preferable; but where the beneficial action of the fertilizers is to be maintained for several years, bone meal and peat are better.

"The use of anaerobic conditions has no advantage over the aerobic method, but is, instead, far more difficult to manipulate."

Observations on an important group of soil bacteria. Organisms related to *Bacillus subtilis*, F. D. CHESTER (*Delaware Sta. Rpt. 1903, pp. 42-96, figs. 12*).—This is a preliminary report on the morphology, cultural features, chemical functions, classification, and description of this group of organisms which is understood to include "those members of the genus *Bacillus*, as defined by Migula, which produce spores, liquefy gelatin, and grow under aerobic conditions." The investigations here reported covered a period of nearly 2 years and involved the comparative study of a large number of cultures.

On nitrogen assimilation by lower organisms, B. HEINZE (*Landw. Jahrb., 35 (1906), No. 6, pp. 889-910*).—Accounts are given of studies and discussions of nitrogen assimilation by nitrogen-collecting bacteria (alinit and root-tubercle bacteria), fungi, algæ, and *Azotobacter* organisms. The importance of the fixation of free nitrogen from the standpoint of practical agriculture is also considered.

There was practically no fixation of nitrogen by alinit and pure cultures of root-tubercle bacteria in the experiments made by the author in media free from and containing nitrogen. The same was true in culture experiments with *Phoma beta*, *Aspergillus niger*, *Penicillium glaucum*, and *Mucor stolonifer*. In experiments with Dematium-like molds and yeasts obtained from ordinary cultivated soil and of *Streptothrix*-like fungi from fallow soil there was some fixation, but this is ascribed only indirectly to the organisms named in that they are believed to have furnished food for other organisms which brought about the fixation. This indirect action is due to supplying organic food and also to the fact that the fungi dissolve lime phosphate, which favored the growth of the nitrogen-fixing organisms.

In culture experiments with *Chlorella* derived from ordinary cultivated soil, fallow soil, and sandy soils there was no appreciable fixation of nitrogen. With both pure and impure cultures of *Nostoc* there was decided fixation of nitrogen when proper conditions of food, temperature, etc., were maintained. It was observed in these experiments that both the blue-green and the chlorophyll-green algæ elaborate glycogen, a very available source of energy for nitrogen-fixing organisms.

Culture experiments with different *Azotobacter* organisms under a variety of conditions led to the conclusion, among others, that dibasic and tribasic potassium phosphate and dibasic calcium phosphate are especially favorable to the growth of these organisms. The best results as regards temperature were obtained at 20 to 30° C., although the organisms showed more or less activity at temperatures as low as 8 to 10°. Increases of nitrogen, due to fixation by *Azotobacter* organisms, of as high as 250 to 350 per cent were observed in the experiments reported. Pectin and pentosan substances were not as efficient sources of energy as sugar.

It is explained how these organisms gradually build up protein compounds from free nitrogen, and pot experiments are reported which show that the nitrogen of this *Azotobacter* material is much less readily assimilated than that of nitrate of soda. Field experiments on fallow soil are referred to as indicating that decided fixation may be brought about under such conditions

by careful attention to thorough cultivation, aeration, addition of humus (carbon supply), and suitable phosphates.

On some new nitrogen bacteria with autotrophic habits of life, H. KASERER (*Ztschr. Landw. Versuchsst. Österr.*, 10 (1907), No. 1, pp. 37-42).—A preliminary report on studies which have already been briefly noted (E. S. R., 18, p. 534).

The author gives a number of chemical reactions which indicate that ammonia may not only be oxidized to nitrite, but also directly to nitrate and to elementary nitrogen. He has isolated and studied an organism to which he gives the name *Bacillus nitrator*, which oxidizes ammonia directly to nitrate without the intermediate formation of nitrite. The most efficient medium for isolating this organism was found to be a solution containing 1/20,000 of formaldehyde in addition to the usual nutritive substance. He has also isolated and described the action of an organism, for which he proposes the name *B. azotofluorescens*, which oxidizes ammonia, setting free elementary nitrogen without the intermediate formation of either nitrite or nitrate. This organism was easily isolated from culture solutions containing formaldehyde or sodium formate.

The author gives a chemical reaction to show the possibility of the oxidation of elementary nitrogen, and expresses the opinion that very probably there is an organism which can bring about such oxidation. The author's preliminary experiments indicate that the conditions are more favorable for such oxidation in heavy clay and calcareous soils than in light soils.

Apparatus for the preparation of lime nitrogen and ammonium sulphate by the processes of the Cyanid Company of Berlin (*Österr. Chem. Ztg.*, 9 (1906), No. 24, pp. 328-330, figs. 4).—The descriptions and illustrations given in this article are taken from a report on nitrogen fixation and lime nitrogen by G. Erlwein. (See also E. S. R., 18, p. 916.)

The changes and the decomposition products of lime nitrogen in soils, H. KAPFEN (*Fühling's Landw. Ztg.*, 56 (1907), No. 4, pp. 122-127).—The rate of transformation into ammonia of lime nitrogen (at ordinary temperature, at 40° C., and in an atmosphere of carbon dioxide), pure calcium cyanamid, dicyanamid, and cyanamido carbonate of lime, in loam and sandy soils and in glass sand was studied with a view especially to its bearing upon the injurious effects of lime nitrogen when applied as a top-dressing. The transformation of lime nitrogen at ordinary temperature and in an atmosphere of carbon dioxide was very rapid and was practically complete at the end of 23 days in loam soil. In no case was more than a very small percentage of the dicyanamid transformed. The transformation of lime nitrogen at 40° C. was 94.28 per cent in loam, 18.75 in sandy soil, and only 2.81 per cent in glass sand. The other products showed lower rates of transformation, but these were highest in the loam soil and lowest in the glass sand.

These experiments are a continuation of those by Immendorff and the author which indicated that the first poisonous effects observed when lime nitrogen was applied as a top-dressing on acid soils are due to cyanamid, the later effects to dicyanamid.

Experiments with lime nitrogen as a fertilizer, B. SCHULZE (*Fühling's Landw. Ztg.*, 56 (1907), No. 5, pp. 145-159).—Series of pot experiments are reported (1) with barley, oats, mustard, spurry, buckwheat, and carrots to determine the relative efficiency of lime nitrogen, nitrate of soda, and sulphate of ammonia on these crops under different cultural conditions; (2) to determine whether the full efficiency of lime nitrogen is obtained by winter applications; (3) with oats followed by mustard to determine the influence of the depth of

application on the efficiency of the lime nitrogen; and (4) to determine the effect of top-dressing with lime nitrogen.

The relative efficiency of the nitrogenous materials on the basis of the increased yield produced, taking nitrate of soda as 100, was 91 in case of sulphate of ammonia and 86 in case of lime nitrogen for all of the crops except buckwheat, with which the efficiency of the sulphate of ammonia was 100 and of the lime nitrogen 77. On the basis of the utilization of the nitrogen, the relative efficiency of the 3 materials was nitrate of soda 75, sulphate of ammonia 58.1, and lime nitrogen 46.6.

The results indicate that there is a considerable loss of nitrogen from lime nitrogen when the material is applied in the winter. The best results were obtained by incorporating the lime nitrogen with the soil to a depth of at least 25 cm. Decidedly injurious effects were observed when the material was used as a top-dressing or mixed with the soil to a shallow depth.

Culture experiments with synthetic nitrate of lime, T. SCHLOESING, JR. (*Bul. Soc. Nat. Agr. France*, 66 (1906), No. 9, pp. 727-731; *abs. in Rev. Gén. Agron., n. ser.*, 2 (1907), No. 1, pp. 9-11).—Experiments in different parts of France with the product manufactured by the electrical process at Notodden, Norway, are reported. The basic nitrate of lime was compared with nitrite and nitrate of lime and nitrate of soda on wheat, oats, potatoes, hay, and grapes on a variety of soils. In general the different fertilizers were about equally effective.

Experiments with nitrogenous fertilizers at the Halle experiment station during 1905 and 1906, SCHNEIDEWIND (*Landw. Wchschr. Sachsen*, 9 (1907), No. 9, pp. 87-89; *Mitt. Deut. Landw. Gesell.*, 22 (1907), No. 5, pp. 36-39).—A large number of comparative plat tests of nitrate of soda, sulphate of ammonia, and lime nitrogen on barley, rye, wheat, potatoes, and sugar beets on 4 typical soils are reported. The relative efficiency of the nitrogenous fertilizers on 3 of these crops, taking nitrate of soda as 100, was as follows: Barley—sulphate of ammonia 92, lime nitrogen 77; potatoes—sulphate of ammonia 99, lime nitrogen 95; sugar beets—sulphate of ammonia 95, lime nitrogen 72; or, averages for all 3 crops of 95 for sulphate of ammonia and 81 for lime nitrogen.

The influence of applications of lime and magnesia on phosphate fertilizing, F. WESTHAUSSER and W. ZIELSTORFF (*Landw. Vers. Stat.*, 65 (1907), No. 5-6, pp. 441-447; *abs. in Jour. Chem. Soc. [London]*, 92 (1907), No. 534, 11, p. 296).—A series of experiments on mustard grown in zinc pots containing 6.5 kg. of ordinary field soil poor in plant food, especially lime and magnesia, to which phosphoric acid in water-soluble form was applied at rates of 50 and 100 kg. per hectare, and Thomas slag at the rate of 100 kg. per hectare, is reported. All of the pots received a basal fertilizer of sodium nitrate and potash salts, and in different cases calcium carbonate, magnesium carbonate (separately or in mixture), gypsum, caustic lime, and caustic magnesia were also applied in varying amounts with the other fertilizers. All of the lime and magnesia compounds except gypsum reduced the yield when used in connection with soluble phosphate, even when the latter was used at the rate of 100 kg. per hectare. The injurious effect was more marked in the case of magnesia compounds than in case of lime compounds. In the case of Thomas slag the addition of moderate amounts of lime or magnesia compounds increased the yield in every case. Large applications of lime and especially magnesia reduced the efficiency of the slag.

The value of crude ammonia, M. DE MOLINARI and O. LIGOT (*Bul. Agr. [Brussels]*, 23 (1907), No. 2, pp. 172-174).—In continuation of previous work (E. S. R., 18, p. 621) the authors report examinations of 6 samples of crude ammonia from different sources. In these the ammoniacal nitrogen varied from

0.42 to 2.28 per cent, the organic nitrogen soluble in water from 0.21 to 1.96 per cent, the organic nitrogen insoluble in water from 1.78 to 7.24 per cent, and the total nitrogen from 5.01 to 9.98 per cent. It is pointed out that in view of these wide variations in composition this material should be bought only upon analysis.

Fertilization of cane lands, F. B. CARPENTER (*La. Planter*, 38 (1907), No. 7, pp. 109, 110).—This is a paper which was read before the Louisiana Sugar Planters' Association, discussing the soil and fertilizer requirements of sugar cane, the best sources of plant food, and the best methods of mixing and applying fertilizers for this crop. The following general formula is recommended: Available phosphoric acid 6 to 7 per cent, nitrogen 5 to 6 per cent, potash 3 to 4 per cent. "The materials, especially the nitrogen, should be selected so as to give the growing crop a continuous supply of plant food and also to avoid danger of large losses by heavy rainfalls."

Report of the State chemist of Florida, 1905 and 1906, R. E. ROSE (*Bul. Fla. Agr. Dept.*, 17 (1907), No. 1, pp. 124).—This report deals mainly with fertilizer and feeding-stuffs inspection and the fertilizer industry in the State, but also discusses the preparation of insecticides and fungicides, the manufacture of cane sirup in the South, the production of Sumatra and Havana tobacco, the need of a pure-food law, and the importance of developing farmers' institutes and agricultural and technical education in the State.

The analyses made during the year include 239 official samples of fertilizers, 231 samples of special fertilizers, 160 official samples of feeding stuffs, 37 special samples of feeding stuffs, and 135 samples of miscellaneous materials (waters, minerals, soils, etc.). Of the 239 official samples of fertilizers the average composition was, ammonia 3.89 per cent, available phosphoric acid 6.47 per cent, and potash 7.85 per cent, these percentages in every case being slightly above the average guaranteed analyses. A number of formulas for fertilizer mixtures for vegetables and for cotton are given.

Fertilizer analyses, A. J. PATTEN and DOROTHEA MOXNESS (*Michigan Sta. Bul.* 239, pp. 15).—Analyses of 134 brands representing the product of 21 firms are reported.

Commercial fertilizers, J. L. HILLS and C. H. JONES (*Vermont Sta. Bul.* 126, pp. 17-40).—Analyses and valuations of samples representing 57 brands are reported.

AGRICULTURAL BOTANY.

Seeds and plants imported during the period from December, 1903, to December, 1905. Inventory No. 11, A. J. PIETERS (*U. S. Dept. Agr., Bur. Plant Indus. Bul.* 97, pp. 255).—This inventory of seeds and plants imported by the Bureau of Plant Industry for experimental purposes covers the period from December, 1903, to December, 1905, and embraces nearly 7,000 items. It represents the collections of H. L. Bolley, E. A. Bessey, L. R. Jones, T. H. Kearney, and others, and gives not only the names of the new introductions, but also embodies notes made at the time of the collection by the agricultural explorers.

The relation of temperature and humidity to the germination of seed of certain grasses, C. DENEUMOSTIER (*Bul. Agr. [Brussels]*, 22 (1906), No. 7, pp. 983-998).—Studies were made to determine the optimum temperatures and moistures for the germination of the seed of Italian and perennial rye grass, meadow fescue, tall oat grass, timothy, crested dogtail grass, and velvet grass.

For the rye grasses, meadow fescue, and tall oat grass the germination bed

should be kept at not less than 60 per cent of saturation, while for timothy, crested dogtail, and velvet grass it should in no case exceed 60 per cent of saturation. A constant temperature of about 25° C. gave the best results for the rye grasses, timothy, and velvet grass, while for the others a variable temperature of 18 hours at 25° C. and 6 hours at 30° C. proved best.

The influence of sea water on the germination of seed, S. BIRGER (*Bot. Centbl., Beihefte, 21 (1907), 1. Abt., No. 3, pp. 263-280*).—In studying the distribution of plants by means of ocean currents, the author was led to carry on some experiments to test the effect of sea water on the germination of the seed of 27 species of Scandinavian plants. Equal lots of seed were subjected for 30 days to sea water containing 3.4 per cent of salt, to fresh water, and similar lots were placed to germinate between filter papers moistened with tap water.

With many species the sea water destroyed the vitality of the seed, while with others it had little or no effect. In some instances more seed germinated after being in sea water for 30 days than when in fresh water for a like period, and some gave even higher percentages than when germinated directly between the filter papers. The effect of the salt water depends upon its osmotic action, which in turn is limited by the structure of the seed coats. It appears that sea water may possibly exert some influence on the enzymes in the seeds.

A tabular list is given showing the results of several investigators along the line of experiments indicated.

The germination of orchids, N. BERNARD (*Report of the Third International Conference, 1906, on Genetics. London: Roy. Hort. Soc., 1907, pp. 392-396, fig. 1*).—The author gives an account of his investigations on the germination of orchid seed, which seem to indicate that there is a close connection between the germination of the seed of orchids and the species of fungi associated with them. The fungi are capable of living apart from the roots of the plants, but the orchids do not seem to develop except in the presence of the fungi. This was shown by experiments in which the seeds of a number of orchids were aseptically treated, placed in sterilized tubes with a nutritive solution, and kept for months in suitable conditions of light and temperature. Under these conditions the seeds become swollen and later they assume a green color, but their growth remains insignificant. On the other hand, if the proper fungi are sown with the seeds the germination begins almost immediately and proceeds in the regular manner.

The author believes that orchids are by no means the only plants which are benefited by some such association with fungi.

The cross inoculation of Leguminosæ and other root-tubercle bearing plants, W. B. BOTTOMLEY (*Rpt. Brit. Assoc. Adv. Sci., 1906, pp. 752, 753*).—A brief account is given of experiments conducted to test the possibility of cross inoculation between the organisms found in the root tubercles of acacia, alder, ekeagnus, and various Leguminosæ. The acacia tubercles were obtained direct from wattles from Western Australia, the other material being from the Botanic Gardens, Regent's Park. The nodules were sterilized, cut under sterile conditions, and small portions transferred to nitrogen-free cultures. After incubation for several days, the material was used to inoculate pots of sweet peas and tares which were growing in sterilized sand. At the end of 4 weeks' growth the plants were examined and it was found that every plant in the inoculated set bore tubercles, while not a single one was found on the uninoculated plants.

The formation of slime or gum by Rhizobium leguminosarum, R. G. SMITH (*Proc. Linn. Soc. N. S. Wales, 31 (1907), pt. 2, pp. 264-294*).—The production of slime by *R. leguminosarum* under certain conditions of cultivation

has been noticed by many investigators, and the presence of this slime is considered a normal function of the organism.

The author has studied a number of races of this organism from plants of various kinds. He has found that slime is formed by a majority of the races upon solid media, and that, as a rule, for its formation the presence of sugar and a source of nitrogen are required. Some races of organisms were found to produce slime, while others did not. The most suitable sources of nitrogen were asparagin and nitrates, and, as a rule, an optimum temperature of 22° C. is to be preferred, although with a race obtained from the black locust the optimum was 26° C.

The experiments on the physiological activities of the various races of the micro-organism showed that after their isolation from the root nodules they all differed. With regard to the function of the micro-organism in the nodule there is said to be strong evidence that it is to produce slime which may be closely related to the carbohydrates of the nucleoprotein molecule. The slime in all likelihood is partially utilized in the formation of the nodules. There is in this respect a true symbiosis so far as the nodules are concerned. The slime may also be transported to other parts of the plant where it is utilized, but there is no evidence to show that the albuminoids of the micro-organisms are utilized by the growing plant, as the majority of them still retain their chromatin. The formation of slime was found proportional to the nitrogen supplied, and there appeared to be no fixation of nitrogen in pure cultures.

The inconsistency of the results hitherto obtained in the inoculation of leguminous crops with bacterial cultures is believed by the author to be due partly at least to the fact that the slime-forming function of the micro-organism had not been recognized and races incapable of slime formation had been used.

The structure of *Rhizobium leguminosarum*, R. G. SMITH (*Proc. Linn. Soc. N. S. Wales*, 31 (1907), pt. 2, pp. 295-302, pls. 2).—In a previous publication (E. S. R., 12, p. 314) the author concluded from his studies of *R. leguminosarum* that it was a form of yeast, but subsequent studies have led him to the conclusion that it is a compound micro-organism and consists of cocci, micrococci, or diplococci, the chromatin of which may be swollen or condensed within a tubular, straight, or branching rod or capsule. Since the *Rhizobium* cell is a tubular capsule containing spherules it is easy to understand that by an increase in the number of these spherules the cell may become misshapen, and irregular forms, such as T, Y, and other shapes, be produced.

The distribution of prussic acid in the vegetable kingdom, M. GRESHOFF (*Rpt. Brit. Assoc. Adv. Sci.*, 1906, pp. 138-144).—In a paper presented before this association, an abstract of which has already been noted (E. S. R., 18, p. 729), a list is given of species of plants in which hydrocyanic acid is known to occur, and the synthesis and function of hydrocyanic acid are discussed.

The author recognizes 2 forms under which hydrocyanic acid occurs in plants, one in combination with acetone and the other with benzaldehyde. In the Rosaceæ and many other plants the hydrocyanic acid is said to occur in the latter form, and by many physiologists it is believed to have nothing to do with the breaking down or building up of proteids, but that this substance is formed by the plant from sugar and nitrates for its defense. On the other hand, those who have studied the occurrence of hydrocyanic acid in *Paugium edule* and other tropical plants are inclined to agree with Treub that it is a stage in the normal formation of proteids in plants.

The chemical aspects of cyanogenesis in plants, W. DUNSTAN and T. A. HENRY (*Rpt. Brit. Assoc. Adv. Sci.*, 1906, pp. 145-157).—It is said that while in all plants in which cyanogenesis has been investigated some free hydrocyanic acid may exist, there is always present a cyanogenetic glucosid which is

readily decomposed by an associated enzyme yielding acid. A number of these glucosids are mentioned and their chemical formulas and reactions are given. Among those described are amygdalin, mandelic nitrile glucosid, sambunigrin, prulaurasin, dhurrin, lotusin, phaseolumatin, etc. Among the enzymes associated with these glucosids the authors briefly characterize emulsin, lotase, gyno-cardase, and maltase. The physiological significance of cyanogenesis is discussed at considerable length.

The translocation of essential oils, E. CHARABOT and G. LALOUE (*Compt. Rend. Acad. Sci. [Paris], 174 (1907), No. 15, pp. 808-810*).—A study was made of *Verbena triphylla* to determine the translocation of the essential oils due to differences in the age of the plants.

Fifty plants at the beginning of flowering were subjected to distillation, the essential oil from the roots, stems, leaves, and inflorescences being collected separately. An average of 337 mg. of essential oil for each plant was obtained, distributed in the different parts as follows: Roots 10 mg., stems 8 mg., leaves 242 mg., inflorescences 77 mg. A few weeks later, after flowering had ceased, a similar lot of plants was examined, and the amount of essential oil found was 280 mg. per plant, of which 16 mg. occurred in the roots, 16 mg. in the stems, 192 mg. in the leaves, and 56 mg. in the inflorescences. During the period of about 3 weeks there had been a considerable translocation of essential oil, as shown by the increase in the roots and stems, but a total loss of 57 mg., which loss is attributed to the utilization by the plant of the essential oils in ripening its fruit.

The weeds of the Province of Prince Edward Island, W. LOCHHEAD (*Prince Edward Isl. Agr. Rpt., 3 (1906), App., pp. I-XXVII, pls. 18*).—Illustrated descriptive notes are given on a number of the more troublesome weeds, with suggestions for their eradication.

FIELD CROPS.

Annual report of the Porto Rico Experiment Station for 1906 [Field crops], D. W. MAY (*Porto Rico Sta. Rpt. 1906, pp. 5-17*).—The progress made in the culture of tobacco, coffee, sugar cane, cotton, rice, forage crops, and fiber plants at the station and in the island are briefly described. The possibilities of a profitable production of these crops in the island, their requirements, and the present state of their culture are discussed.

Demonstration farms, E. G. SCHOLLANDER (*North Dakota Sta. Rpt. 1906, pt. 1, pp. 66-89*).—This report maps out the work for a period of 5 years and gives the results obtained the first season on 6 demonstration farms in the State. The object of the work is to determine in each case what crop rotation is best adapted to that particular neighborhood, to build up the fertility of the soil by substituting field corn and clover for summer fallowing, and to preserve the moisture and clean the land by extra tillage.

The results of soil moisture determinations and the rainfall and frost records at different points are given in tables.

Crop work at the northern substation farms, R. A. MOORE and E. J. DELWICHE (*Wisconsin Sta. Rpt. 1906, pp. 275-280, figs. 3*).—Swedish Select oats at Iron River yielded 27 bu. per acre, weighing 38.6 lbs. per measured bushel, and barley 26 bu., weighing 49.2 lbs. Corn was fully matured before October 5, before heavy frost, and gave a total yield of 18,500 lbs. per acre, the grain amounting to 47.7 bu. of shelled corn. An early variety of soy beans produced 2 tons per acre of well-cured hay, and a row left in the field produced a good quality of well-ripened beans before frost. One-fourth acre of Kleinwanzleben sugar beets yielded at the rate of 9 tons per acre, and showed a test of 93.3 in

purity and 16.9 in sugar content. At Ashland, Swedish Select oats yielded 16 bu., weighing 30 lbs. per bushel, and at Superior 9 bu. per acre, also weighing 30 lbs. per bushel. The yield of barley at Ashland was 16.5 bu., with the weight per bushel 49.2 lbs.

Report of experimental work on the Randolph County farm, 1906, G. I. CHRISTIE (*Indiana Sta. Circ. 5, pp. 4*).—This is a report on the work conducted at the Randolph County farm, recently established as a county farm experiment station.

Twenty-eight varieties of corn were under test. The results of the first year suggest that the farmers of the county possess some valuable strains of varieties of corn for their locality, that imported varieties do not prove as satisfactory as home-grown varieties, and that many farmers are growing strains or varieties not of the highest producing power.

Field experiments, A. R. WILTON, E. J. DELWICHE, and E. R. JONES (*Wisconsin Sta. Rpt. 1906, pp. 181-200, figs. 3*).—Soil improvement experiments are in progress on sandy, marshy, and red clay soils.

On sandy soil, at Sparta, the best crop of oats was secured where either barnyard manure or peat, potash, and acid phosphate was applied. The results indicate that the chief lack in the soil for this crop is nitrogen. Peat, with phosphoric acid and potash, was not equivalent to barnyard manure in growing corn. A yield of 38.7 bu. per acre was obtained on the manured plot, while the check plot yielded only 7 bu. For potatoes the effect of the fertilizers applied was similar to that with corn, with the exception that peat did not seem so beneficial. The application of phosphoric acid and potash is considered of little use on this soil until its nitrogen content has been increased.

The chief problem on the field at Iron River, as on that at Sparta, is the retention of a sufficient supply of humus to give the soil a good water-holding capacity. The largest yield of marketable potatoes was secured on the plot receiving peat, phosphoric acid, and potash, and the smallest yield on the plot receiving no fertilizers. The yield of corn on the different plots varied from 28.3 bu. to 51.5 bu. per acre, but the variation in the natural fertility of the field makes the yields on the different plots of little value. The effect of peat and manure on oats was very noticeable.

In reclamation work on marshy soils at Marinette it was found that phosphoric acid is the element most needed, and that potash is also beneficial.

Notes are also given on cultural work carried on at different points. On the red clay lands near Superior the best stand and the best yield of corn was obtained where tile had been placed 40 ft. apart. Larger distances between tile lines gave less satisfactory results.

Experiments with grains and forage plants, 1906, R. A. MOORE and A. L. STONE (*Wisconsin Sta. Rpt. 1906, pp. 240-258, figs. 3*).—Of 27 varieties of oats under test Sixty Day and Kherson, which gave good results last season, again produced good yields. The Sixty Day showed its characteristic earliness, but was weak and lodged badly. Swedish Select continues to give good yields and to prove most satisfactory on high and lighter soils.

Sixty-four varieties of barley were compared at the station this season, and a cooperative test of Oderbruck barley was carried on by members of the Wisconsin Experiment Association. At the station the beardless, hullless, and 2-rowed barleys showed weakness of straw and did not fill out well. The best yields of grain were produced by Silver King, Manshury, and Oderbruck, the yields being 61.3, 60.6, and 60.1 bu. per acre, respectively. These 3 varieties matured in 98 days.

In the cooperative test with Oderbruck barley an average yield of 41.8 bu. per acre was secured on fall plowing, and 35.9 bu. on spring plowing. Drilling

gave an average yield of 41.1 bu., as compared with 39.6 bu. where sown with a seeder. Drilling on fall plowing gave an average yield of 43.3 bu., and on spring plowing 37.3 bu., as compared with 41.2 bu. and 35 bu., respectively, where a seeder was used. In 4 cases where the barley was sown on land not plowed, but worked up carefully with a disc plow, an average yield of 22.2 bu. was secured.

The row test of Wisconsin No. 7 corn, begun in 1905, showed that the yields of seed corn and marketable corn had been materially increased over those of a year ago. The average yield per row in 1905 was, seed corn 22.6 lbs., marketable corn 97 lbs., and mibbins 7.2 lbs.; and in 1906, seed corn 53.1 lbs., marketable corn 132.8 lbs., and mibbins 13 lbs. In 1906 the average yield per acre on 4 10-row plats was 75 bu. While the heavy yield was largely due to a favorable season, it was noticed that the increase of seed corn was greater in proportion than that of the mibbins, and this fact is considered due to the selection of seed.

For 2 years seed has been selected from stalks bearing a single large ear and compared with seed from stalks bearing 2 good ears. The results at present show a decrease in the weight of single ears in one case and an increase in the other, with a similar result in the double-ear strain. The total yield of corn was greater where the selection was made to increase the number of single ears than where it was made to increase the number of double ears. The total yield from the single-ear strain was 1,324 lbs. of corn from 8 rows each 396 ft. long, and 1,197 lbs. from the double-ear stalks. Generally the double-ear stalks produced small and poorly formed ears.

Of the crosses made in 1905 that of Wisconsin No. 8 on Toole North Star was most promising, and the crop of this cross during 1906 seemed to show that this new variety has a larger ear than the Wisconsin No. 8 and ripens earlier than North Star. The corn was ripe and cut September 26, 126 days after planting, while in 1905 the ripening period of Wisconsin No. 8 was 120 days and of North Star 133 days.

An experiment in summer seeding of alfalfa was begun in 1905. The alfalfa was sown without a nurse crop on July 14 and August 12. The next season, while 1.5 tons of field-cured hay per acre was secured on the July seeding, both plats were too weedy to be successful and were plowed up and sown to winter grains. The following season alfalfa was sown on April 23 and 24 with barley as a nurse crop, on May 11 without a nurse crop, and on June 1 on ground that had been kept free from weeds by cultivation during the season. The best stand was secured by seeding in April with a nurse crop. As determined from members of the Wisconsin Experiment Association, clover and alfalfa were badly winterkilled in the southern half of Wisconsin during the winter of 1906. In the northern part of the State the crops were protected by snow and suffered little. Alfalfa proved to be as hardy as medium red clover.

Brief notes are given on different plant-breeding experiments in progress.

Report of the chemist [Field crops], C. L. PENNY (*Declarac Sta. Rpt. 1903, pp. 97-112*).—*Cover crops*.—A study of various cover crops was made and the yield and composition of the portion of the crops above ground and of the roots is tabulated, together with their money valuation as green manures. Data with reference to the moisture content of the surface soil under the different crops are also given.

The soy bean furnished the greatest weight of air-dry matter in the tops alone, and the cow-horn turnip the greatest air-dry weight of roots. In the yield of tops and roots the soy bean ranked highest with 3½ tons per acre, being followed by rape with a little over 3 tons, crimson clover and cow-horn turnip with a little less than 3 tons, alfalfa, red clover, and cowpeas with about

2 tons each, and vetch with about $1\frac{3}{4}$ tons per acre. The soy bean produced a total yield of nitrogen of about 140 lbs. per acre, being closely followed by crimson clover, rape, and vetch, while the cowpea gave 69 lbs. per acre, or about half as much as the soy bean.

By rating the nitrogen at 12 cts., the potash at 5 cts., and the phosphoric acid at 3 cts. per pound, the money value per acre of these constituents for the best 8 cover crops ranged from \$17.90 for red clover to \$25.84 for rye and vetch, the average being \$21.48. Of this average value the nitrogen represented \$15.21, the potash \$5.13, and the phosphoric acid \$1.14, being 71, 24, and 5 per cent of the whole value, respectively. In crimson clover, which has the most phosphoric acid relatively and absolutely, this constituent represented only 8 per cent of the whole value. The highest potash value, \$8.07 per acre, was found in the rape, where it constituted 32 per cent of the whole. The cow-horn turnip with \$7.14, and rye and vetch with \$6.76 for potash, stood next, but in each of these this element constituted 34 per cent of the whole.

Soil moisture determinations were made on plowed and unplowed soil. On an average for the season the unplowed land contained 3.7 per cent less moisture than the plowed soil. During the autumn and winter months the subsoil of the plowed portion contained on an average 3.7 per cent more moisture than the unplowed portion.

Selective propagation of corn.—Analyses were made of 335 ears of seed corn secured throughout the State, and it was found that the protein content ranged from 8.31 to 11.31 per cent. Directions for the selection of seed corn are given.

Crop production in western Nebraska, W. P. SNYDER and E. A. BURNETT (*Nebraska Sta. Bul. 95, pp. 34, figs. 8*).—This bulletin contains a description of the substation at North Platte, together with a report of the results obtained with different kinds of crops. The requirements of dry-land farming are also outlined.

Of a number of durum wheats grown, Black Don and Velvet Don have given the highest yields. In variety tests of 3 years the highest yielding durum wheat gave an average yield per acre of 18.5 bu., and the lowest of 13.9 bu., while the common spring wheat yielded 7.2 bu. The average yield per acre during the 3 years was with durum varieties $2\frac{1}{2}$ times that of the common spring wheat. The results of winter wheat tests showed that Kharkof outranked Turkey Red in yield. It was observed that it is advisable to sow winter wheat before September 15. Seeding 2 pk. per acre gave practically the same yield as seeding 4 or 5 pk.

In 1906, Sixty Day oats yielded 47.8 bu. and Kherson 47 bu. per acre, but the results of all tests made during 3 years placed Kherson first and Sixty Day and Texas Red a close second and third, respectively. The highest yield of oats secured at the substation was 52 bu. per acre on a 5-acre tract, but yields of 75 and 80 bu. are reported by farmers growing Kherson oats from seed secured at the substation.

Beldi and Telli barley, 2 Algerian varieties, did not yield as well as common bearded barley, which on 1 plat produced 44.4 bu. per acre, as compared with 29.4 bu. for hullless and 17.8 bu. for beardless. Emmer did not appear to yield as heavily as barley.

The average yields of different varieties of corn grown for 2 years ranged from 39.8 bu. for Pride of the North to 45.9 bu. for Silver Mine. Calico, yielding 45.6 bu. per acre, is considered the best corn tested. This variety and Pride of the North matured fully.

The results with different annual forage crops are also briefly noted. The highest average yields for 2 years from cane, Kafir, and milo were secured when

these crops were drilled in double rows 7 in. apart, with each pair of rows 35 in. from the next pair. Cane and Kafir produced about equal quantities of excellent forage. Dwarf milo also gave good results, but showed no advantage over cane, with the exception that the seed is perhaps better for feed. German and Siberian millet yielded only about one-half as much per acre as cane, which, with the exclusion of alfalfa, is considered the main forage crop for western Nebraska. The yield of seed on 3 plats of brome grass ranged from 157 to 700 lbs. per acre. The heaviest yielding plat had been in alfalfa previous to being seeded to brome grass. Directions for sowing brome grass are presented in detail.

The experience with alfalfa at the station and in its vicinity is given, together with notes on its culture especially for seed.

Principles of tillage and rotation, W. H. DAY (*Ontario Dept. Agr. Bul. 156, pp. 8*).—This bulletin discusses tillage in relation to soil moisture and considers, in addition, the necessity of the proper conditions in soil temperature, air supply, and the sanitary environment of the roots of the plants.

Pot experiments were conducted to determine the water requirements of different crops. In 1905, a season with ordinary rainfall, wheat required 22.60, peas 27.38, barley 18.52, and oats 24.15 in. of water, and in 1906, a wet season, wheat used 17.32, peas 18.32, barley 18.82, and oats 18.47 in. of water. It is concluded that during a wet season crops do not use as much water as during a dry one, although the supply is much more abundant. In these experiments during the wet season the crops required one-half more than the rainfall, and it is pointed out that any soil, whatever its condition, retains enough of the spring and winter precipitation to supply this deficiency.

A loam soil was allowed to dry out until the grain growing in it began to wilt. The water content of this soil at the wilting point was found to be 7.3 per cent.

Forage crops of high, medium, and low protein content, H. SNYDER (*Minnesota Sta. Bul. 101, pp. 229-256*).—The protein content and the composition of the dry matter of a list of forage crops and forage-crop combinations are given and briefly discussed. The dry matter and protein content of corn fodder at different stages of growth are shown in a table, as is also the composition of silage and that of corn smut.

It was found that corn fodder, timothy hay, rape, pasture grass, and hay crops from mixed grasses were materially influenced in composition by the use of farm manures. Less fiber and from 25 to 30 per cent more protein were secured on soils in a good state of fertility than on similar soils low in plant food. Leguminous crops like clover, alfalfa, and peas did not appear to be as susceptible to the influence of fertilizers in increasing the protein content as crops like corn fodder and rape.

An examination of a number of samples of clover, alfalfa, pea, bean, and millet seeds of known quality showed each sample to contain 2 distinct types of seed, 1 of high and the other of low protein content. The high protein seeds were darker in color and more corneous in character than the low protein seeds. It is believed that by selecting seeds on this basis, forage crops of the maximum protein content may be produced in the same way as has been accomplished with wheat and corn.

Analyses of 18 samples of the more common weeds showed that many of them assimilate large amounts of soil nitrogen, and it was found that when they were harvested with grain crops the amount of nitrogen removed by them from the soil was often larger than that contained in the grain.

The dry matter of nearly matured rape was found to contain about the same amount of protein as clover. Rye fodder, prairie hay, and millet showed about the same general composition in feeding value as timothy hay produced under

similar conditions and cut at the same stage of growth. Pasture grass and hay from mixed grass seeds and some clover contained more nutrients, especially when grown on well cultivated and manured land, than timothy, red top, or blue grass alone.

A comparison of methods for the inoculation of leguminous crops, R. A. MOORE and E. J. HASTINGS (*Wisconsin Sta. Rpt. 1906, pp. 281-284*).—The methods employed are outlined, and the nature and origin of the cultures used are described. The use of artificial cultures for the production of nodules upon soy beans and alfalfa was not successful, while the inoculation of these crops with infected soil produced nodules in abundance the first year.

The vitality, adulteration, and impurities of clover, alfalfa, and timothy seed for sale in Iowa in 1906, L. H. PAMMEL, R. E. BUCHANAN, and CHARLOTTE M. KING (*Iowa Sta. Bul. 88, pp. 69, figs. 39, maps 2*).—Earlier work of this kind at the station and elsewhere is briefly reviewed and the results of investigations with clover, alfalfa, and timothy seed are reported.

In 130 samples of red clover seed the percentage of impurities was determined by weight and averaged 1.93 per cent. The highest percentage of impurities was 33.3 and only 2 samples consisted of pure seed. Of 118 unweighed samples of red clover seed, 76 were found to contain yellow foxtail (*Setaria glauca*), 68 timothy (*Phleum pratense*), 61 curled dock (*Rumex crispus*), 57 green foxtail (*Setaria viridis*), 48 lady's thumb (*Polygonum persicaria*), 46 rib grass (*Plantago lanceolata*), 46 Rugel plantain (*Plantago rugelii*), 37 rough pigweed (*Amarantus retrofractus*), 34 sheep's sorrel (*Rumex acetosella*), 34 crab grass (*Panicum sanguinale*), 30 dooryard plantain (*Plantago major*), 25 lamb's quarter (*Chenopodium album*), and 20 bracted plantain (*Plantago aristata*). Other weeds occurred in a smaller number of samples, and sand was found in 37 samples.

Of a total of 248 samples of clover seed, 98 contained rib grass, 35 bracted plantain, 21 Canada thistle, and 10 dodder. Five typical poor samples of clover seed contained 10.301 per cent of impurities, and 5 typical good samples 0.096 per cent.

The principal impurities found in white clover seed were sheep's sorrel, Rugel plantain, bracted plantain, timothy, curled dock, lamb's quarter, blue grass (*Poa pratensis*), and cinquefoil (*Potentilla*).

In 31 weighed samples of alsike clover seed, the impurities amounted to 3.437 per cent, and of 19 unweighed samples 18 contained timothy and 11 sheep's sorrel. Of 10 samples of alfalfa seed examined, 8 contained rib grass. A study of 24 samples of timothy showed that none of the weed seeds they contained were other than those of species common in Iowa. In a second lot of 30 samples examined, 20 contained sand and 15 red clover.

The following average results were secured in germination tests: Red clover tested in March, plump seeds 79.8 per cent, shrunken seeds 30.9 per cent; red clover tested in November, plump seeds 48.62 per cent, shrunken seeds 25.23 per cent; mammoth clover, plump seeds 72 per cent, shrunken seeds 71 per cent; medium red clover, plump seeds 87.61 per cent, shrunken seeds 46.88 per cent; alfalfa tested in March, plump seeds 56.91 per cent, shrunken seeds 24.16 per cent; alfalfa tested in November, plump seeds 20 per cent, shrunken seeds 10 per cent; timothy, plump seeds 64 per cent, shrunken seeds 20.7 per cent.

A general discussion of the impurities found in agricultural seeds and an alphabetical list of all impurities found in the samples examined in these investigations are given.

Soy beans, cowpeas, and other forage crops, A. T. WIANCKO and M. L. FISHER (*Indiana Sta. Bul. 120, pp. 439-460, figs. 6*).—Historical notes on the soy bean and cowpea are given, the uses, value, culture, and cost of production

discussed, and a number of varieties of the 2 crops described. Notes are also given on a number of miscellaneous forage crops.

The best average yield of soy beans, 21.3 bu. per acre for 3 years, was secured from planting 24 lbs. of seed per acre in drills 32 in. apart and cultivating the crop. A plat broadcasted at the rate of $1\frac{1}{2}$ bu. of seed per acre gave an average yield for the 3 years of only 10.7 bu. The common wheat drill was found the most convenient and most satisfactory machine for planting both soy beans and cowpeas, and detailed directions for its use in this connection are given.

The earliest variety of soy beans, Very Dwarf Brown, ripened about August 19, and the latest, Medium Early Yellow, about October 21. The late varieties gave as a rule heavier yields than the early maturing sorts. The largest average yield, 22.2 bu. per acre, was secured from Medium Green, and the smallest, 9.5 bu., from Very Dwarf Brown.

Among the varieties of cowpeas grown for forage in 1905, the highest average yield, 7,600 lbs. of hay per acre, was secured from Clay 13458, followed by Iron with a yield of 7,400 lbs. per acre.

In connection with a description of a number of miscellaneous forage plants, a succession of crops for soiling purposes is outlined.

Haymaking at Kenai Experiment Station, P. H. ROSS (*Alaska Sta. Bul.* 3, pp. 13, pl. 1).—The experiments in making hay in 1905 and 1906 are briefly described. All cuttings were either oat hay or native hay (*Calamagrostis lungsdorfii*), with the exception of 1 cutting of barley.

The author recommends cutting oats for hay when in the milk stage and the native grass when in full bloom. The hay should be stirred with a fork to leave it in a loosened condition shortly after cutting, so that the air will pass through it freely. Medium size, well-made cocks are advised so that the rains may do no damage and the curing process may go on. The shortest time in which hay was cured well was 10 days and the longest 25 days.

Alfalfa in Ohio, C. G. WILLIAMS and C. H. KYLE (*Ohio Sta. Bul.* 181, pp. 111-135).—The results with alfalfa at the experiment station and the experience of alfalfa growers throughout the State are reviewed.

It was found that upland clay and sandy first and second bottom lands have produced the heaviest maximum and average yields. All sandy upland and clay first and second bottom lands produced the lowest yields. Good yields and poor yields have been produced on all classes of soils, including muck. It was observed that the presence or absence of drainage, humus, limestone, and inoculation, and the degree of perfection of the seed bed, were usually the controlling factors in the growth of the crop. The yields on clay upland with natural surface drainage were 12 per cent greater where tiles were also used. Sandy soil or soil with a very poor subsoil is considered as usually not sufficiently retentive of moisture to insure certain results on upland. The soils which heaved the alfalfa were either poor in drainage or in humus, or in both combined.

The average yields from soils rich, fairly rich, and poor in humus were respectively 4.25, 3.75, and 3.33 tons per acre. At the station an alfalfa plat receiving 8 tons of manure per acre gave a yield of 10,275 lbs., or 1,347 lbs. per acre more than unfertilized plats. The use of lime on acid soils is recommended, and it is pointed out that fields on hillsides and upland usually become acid before those on bottoms. Inoculation with soil was found much better than inoculation with liquid cultures. It is stated that alfalfa may be seeded at any time after spring frosts are over until the middle of August, provided the seed bed is in proper condition.

Corn breeding and registration, C. G. WILLIAMS (*Ohio Sta. Circ.* 66, pp. 14, dgms. 6).—This circular contains a detailed description of growing seed corn

by the ear-row test plan, and presents the rules for the registration of seed corn with the Ohio Plant Breeders' Association.

The corn crop of Delaware, A. T. NEALE (*Delaware Sta. Rpt. 1903*, pp. 7-34).—This article presents some statistical studies based on census reports, discusses the significance of rain in corn culture, describes the beneficial effects which crimson clover may exert upon the corn crop, and gives practical details in the utilization of corn fodder.

It is believed that crimson clover on the land each winter, followed by corn each summer, improves the corn-producing qualities of the lighter lands in Kent and Sussex counties of the State, and that this is probably due to an increase in the water-holding power of the humus derived from the clover crop.

Hops in principal countries: Their supply, foreign trade, and consumption, with statistics of beer brewing, E. MERRITT (*U. S. Dept. Agr., Bur. Statis. Bul. 50*, pp. 34, *dgm. 1*).—This bulletin gives the production of hops in the United States from 1850-1900, and the annual production and commercial movement of this product from 1889-1905, together with the localization of the production in this and the European countries. Figures are also given with reference to the trade and consumption of hops in the United States and abroad. The countries producing a surplus, and those partially or wholly dependent upon foreign hops are enumerated, and the fluctuation in the price of hops is pointed out and discussed.

The data show that the United Kingdom, Germany, and the United States consume the most hops, and that Austria-Hungary, Germany, and the United States are the principal exporting countries. Germany imports from Austria-Hungary and the United States, while France, Belgium, and the Netherlands import from Germany. The United Kingdom supplies its demands from the United States, the Netherlands, Belgium, and Germany. Of the 4 principal hop-producing countries the largest yields per acre are obtained in the United Kingdom and the United States, and the best quality of product is secured in Austria-Hungary and Germany.

The United Kingdom and France require a much larger quantity of hops to the barrel of beer than Germany or other continental countries. The average for the United States is below that of the United Kingdom, Australia, and France, and above that of all other countries represented. The hops from countries where special attention is given to quality bring better prices and are held in higher esteem than American hops, even in our own country. The comparative trade, production, and consumption of hops in the principal countries for 1900-1904, and the yields, exports, and imports of the different countries for 1901-1905, together with the quantities of beer brewed in the different countries for 1890-1904, are given in tables.

Germany, the United States, and the United Kingdom are the 3 principal beer-producing countries of the world. Of the world's total beer production, Germany is represented by 27.8 per cent, the United States by 23 per cent, the United Kingdom by 22.6 per cent, Austria-Hungary by 8.5 per cent, Belgium by 6.1 per cent, and France by 5.7 per cent.

Duty of water on field peas, 1906, H. T. NOWELL (*Wyoming Sta. Bul. 72*, pp. 16, *figs. 13*, *dgm. 1*).—Field peas under the flood method of irrigation showed a wide variation in yield of dry forage and threshed peas, according to the quantity of water applied. On 6 plats the highest yield of dry forage, 4.2 tons per acre, was obtained with nearly 23 in. of water applied in 7 irrigations. The highest yield of peas, 34.75 bu. per acre, was secured when about 20 in. of water was applied in 4 irrigations. The yield decreased with either more or less water. The relation of cost of irrigation to the value of increased yield shows that a duty of water a little under 20 in. will probably give the

most profitable results. Each irrigation delays maturity, and when much over 20 in. of water is used at Laramie peas do not fully mature. These results were obtained with a rainfall of 7.05 in. during the growing season.

A net profit of \$50 per acre is possible by raising pea seed valued at 3 cts. per pound, and a net profit of \$25 to \$30 by raising forage for sale at \$10 per ton, when the proper quantities of water are applied in several light irrigations.

Potato experiments, R. A. EMERSON (*Nebraska Sta. Bul. 97, pp. 26*).—During the past 2 years the station has carried on tests comparing various methods of potato culture, different sizes of seed pieces and quantities of seed, different kinds of seed, and distance experiments.

Seed potatoes produced under a straw mulch the preceding year yielded 47 per cent more in 1905 and 41 per cent more in 1906 than similar seed grown by cultivation. Seed potatoes stored in an ordinary cellar, where they wilted and sprouted badly before planting, gave poor results. The average yield from sound seed was 56 per cent greater than from sprouted seed in 3 separate tests. Of different combinations tried, the best results were obtained from 18 bu. of seed per acre cut in quarter tubers and the pieces planted 12 in. apart. Nearly as good results were obtained from 36 bu. per acre of seed tubers cut in halves and planted 12 in. apart.

An old alfalfa sod plowed up in the fall of 1905 and replowed in the spring seemed to have increased the yield of potatoes only 5 per cent. Planting the seed pieces in furrows made with a lister after plowing increased the yield 28 per cent, as compared with dropping the seed pieces in every third furrow as the plowing was done. Ridging up the ground over the rows of seed pieces when planted, and harrowing the ridges down as the weeds began to grow, increased the yield 53 per cent over leaving the ground level above the rows of planted seed.

Potatoes planted 4 in. deep gave better yields in 1905 than those planted 3 and 5 in. deep, but the tubers were about equal in quality. Planting the seed 1 and 2 in. deep decreased both yield and quality as compared with deeper plantings.

In 1905 7 cultivations gave 47 per cent greater yield than 5 cultivations, but 10 cultivations reduced the yield slightly below that from 7 cultivations. In 1906, from weedy lands, 3 harrowings followed by 4 cultivations produced a yield 132 per cent greater than 2 harrowings and 2 cultivations. The same year, on cleaner ground, 3 harrowings and 4 cultivations increased the yield over 2 harrowings and 3 cultivations by 60 per cent, while with 4 harrowings and 6 cultivations the yield was slightly decreased.

Seven years' experience indicates that mulching is a fairly satisfactory way of growing potatoes on a small scale, although the method is practicable only when the mulching material can be obtained very cheaply. Old hay or straw should be spread about 4 in. deep just before the plants appear and after the ground has been harrowed once or twice since planting. Rather large seed pieces should be planted 2 or 3 in. deep, and the hills should be placed 18 by 18 or 12 by 24 in.

Potato investigations, E. P. SANDSTEN and E. J. DELWICHE (*Wisconsin Sta. Rpt. 1906, pp. 227, 228*).—These investigations were carried on at the substation at Iron River, on land which had been in potatoes for several years, with the exception of $\frac{1}{2}$ acre which was in clover. The land was divided into 4 plats, the first receiving 10 loads of well-decomposed barnyard manure per acre, and the second a dressing of 200 lbs. of nitrate of soda, 200 lbs. of potash, and 300 lbs. of desiccated bone, applied July 2 and 19. The third plat received no fertilizer, and on the fourth a heavy crop of green clover was turned under.

The first plat gave an increase of 13.7 per cent, the second of 10 per cent, and the fourth of 37.2 per cent over the check plat.

Tobacco investigations, E. P. SANDSTEN (*Wisconsin Sta. Rpt. 1906, pp. 201-208, fig. 1*).—Work has been carried on for 3 years in the lines of improving Wisconsin tobacco by breeding and selection, the use and value of commercial fertilizers and barnyard manure in growing the crop, the use of cover crops in this connection, and the proper handling and curing of the leaf.

A variety of Wisconsin-grown Connecticut Havana was selected as a type suited to Wisconsin conditions in the work of improvement by breeding and selection. The object in view was the production of a broader and larger leaf with a more rounded outline than the Connecticut Havana, but retaining the high quality and compactness of this variety. This work at present indicates excellent results.

The fertilizer work has led to the conclusion that the best application consists of 10 tons of barnyard manure, 100 lbs. of nitrate of soda, 150 lbs. of sulphate of potash, and 200 lbs. of desiccated bone per acre.

Very satisfactory results have been secured during 2 years with hairy vetch as a cover crop on tobacco fields. The seed was sown immediately after the tobacco was harvested, at the rate of 60 lbs. to the acre and cultivated in.

A description is given of the shed constructed at the station for the purpose of studying the conditions of curing.

Tobacco breeding, A. D. SHAMEL and W. W. COBEY (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 96, pp. 71, pls. 10, figs. 14*).—This bulletin treats of the variability in tobacco plants and the introduction and acclimatization of varieties, describes the structure and arrangement of the flowers, discusses the necessity for inbreeding, the improvement of the shape of the leaves, their modification in size, and the control of their number on individual plants, considers the production of nonsuckering types of tobacco and of early varieties, and points out the value and desirability of improving the burning quality. Rules are given for the selection of seed plants, and the method of keeping the records of breeding work made in the field, as well as the permanent record, is outlined. Methods of saving seed and a process of separating the seed with a tobacco seed separator are described. The possibility of selecting disease-resistant types is also discussed.

A description is given of a new variety of tobacco produced by seed selection. This new variety is known as Uncle Sam Sumatra and was produced by seed selection begun in a Connecticut shade-grown crop in 1903. The characteristics of the variety are extremely round leaves of fine texture, small fine veins at right angles from the midrib, and a large number of leaves with great uniformity of size and shape from the base to the top of the plants. The quantity of seed produced by the variety is very small, and very few and small suckers develop at any time during the growing season. The pedigree record of the original plants and their progeny shows the following averages: 21 leaves per plant, leaves $20\frac{1}{2}$ in. long and $14\frac{1}{2}$ in. wide, 3 small suckers, plants 6 ft. high, growing period 90 days, length of internode $3\frac{1}{2}$ in., and circumference of stem $3\frac{1}{2}$ in.

Descriptions are also given of the Cooley hybrid and the Brewer hybrid, new varieties produced by hybridization and seed selection, and described in former reports.

Eradication of wild mustard, R. A. MOORE and A. L. STONE (*Wisconsin Sta. Rpt. 1906, pp. 259-269, figs. 6*).—Spraying grain fields with a 20 per cent solution of iron sulphate destroyed practically all the wild mustard plants. It is recommended that the spraying be done on a calm, bright day after the dew has disappeared and at a time when the mustard plants are in the third

leaf, or before they are in blossom. Daisies, cocklebur, bindweed, ragweed, chicory, sheep sorrel, yellow dock, wild lettuce, and many other weeds were partially or wholly eradicated from the fields where these tests were made.

Three acres and liberty, B. HALL ET AL (*New York and London: The Macmillan Co., 1907, pp. 435, pls. 14*).—This book is written with the purpose "to awaken active and earnest thought upon the social betterment of our rapidly increasing population." Among the different subjects discussed are buying a farm, results to be expected, methods of management, gardening, tools and equipment, beds and greenhouses, various uses of land, fruit, flowers, drug plants, novel live stock, and buildings.

HORTICULTURE.

The garden book of California, BELLE S. ANGIER (*San Francisco and New York: Paul Elder & Co., 1906, pp. VII + 141, pls. 20*).—This book contains suggestions for beautifying the home grounds by the use of trees, shrubs, vines, and flowers, of which a large number of varieties are recommended for different forms of planting. Chapters are devoted to simple garden methods, a planting calendar, and a discussion of insect pests and plant diseases and their general remedies.

Among the special subjects considered are the culture of common plants, bulbs, palms and tropical plants, roses and ferns, ferneries, hedges, tree planting and protection, back-yard problems, the making of pergolas, and the equipment of the aviary. In the closing chapter a list is given of some of the most valuable and showy native annuals, together with the varieties of native trees and shrubs recommended.

Report of the horticulturist, C. P. CLOSE (*Delaware Sta. Rpt. 1903, pp. 117-140*).—The following lines of work received especial attention during the season of 1903: The use of nitrate of soda on asparagus, root forcing on fruit trees, orchard cover crops, pruning Kieffer pear trees, commercial fertilizers in apple orchards, fruits in preserving fluids, dipping nursery trees in kerosene and crude petroleum, paint on fruit trees, and special pruning of fruit trees. Previous experiments with the use of nitrate of soda on asparagus have been noted (E. S. R., 15, p. 578).

The outline of the asparagus test was as follows: 200 lbs. of nitrate of soda was used per acre, applied in 4 equal applications 10 days apart, the first application being made 10 days before the cutting began. This experiment was conducted at the farms of 2 cooperators and the results are tabulated. The gain in yield for the fertilized plats over the unfertilized plats is not sufficient to signify any particular benefit from the nitrate of soda.

Previous work with root forcing on fruit trees has also been noted (E. S. R., 15, p. 578). In order to get more data from trees grown 1 year, 12 peach trees and 8 apple trees were planted in the spring of 1902. Of the 12 peach trees 4 had 2 strips of bark about $\frac{1}{2}$ in. wide removed from the roots, 4 had 1 strip removed, and 4 were left as checks. Of the 8 apple trees, 3 had 2 strips of bark taken from the roots, 3 had 1 strip, and 2 were left as checks. The trees were dug the latter part of November and the records of top growth and the grade of the root systems are tabulated. The results obtained in this experiment for the 2 seasons point to the impossibility of forcing a large development of roots from the callus formed as the result of removing these strips of bark from the roots.

Tests were made with a large number of orchard cover crops, both at the experiment station and with cooperators elsewhere, and notes are given as to the behavior of each crop tested.

In the spring of 1903 a pruning experiment was started with Kieffer pears in the 2-year old orchard of F. M. Soper, at Magnolia, in which it was desired to compare the results of early severe with early moderate pruning, and these kinds with late moderate pruning after the trees were in full foliage. The trees had never previously been pruned. As to the results, all that could be determined in 1903 was the extent of growth and appearance of the foliage, which was considerably better on the trees pruned early and severely. Those pruned early and moderately were next best, being much better than the late pruned trees.

An outline is given of commercial fertilizer tests planned to be conducted in apple orchards, in which it was decided to use a fertilizer containing 200 lbs. of nitrate of soda, 85 lbs. of acid phosphate, and 165 lbs. of muriate of potash as the standard formula. Variations of this formula were also to be used in conjunction with cover crops.

In the hope of finding a preserving fluid capable of holding the color and shape of various fruits, the writer made several tests with a great variety of preservatives. Notes are given as to the behavior of apples, peaches, and plums in these different mixtures. In general, no satisfactory preservative was obtained.

A test was made in order to determine what injury would result by dipping nursery trees in a bath of kerosene or crude petroleum for the prevention of scale. A V-shaped trough 8 ft. long was the dipping receptacle, in which the tree was dipped and thoroughly covered with the insecticide. The trunk just above the roots was treated by pouring the insecticide over it. The trees treated included peach, pear, apple, and cherry, and the results are tabulated. The results show more or less severe injury in all cases, whereas in each case the check trees passed through the winter in good shape. The treated apples and pears appeared to suffer less from injury than the peaches and cherries. The use of crude petroleum is somewhat less dangerous than kerosene.

It is sometimes the practice to paint the trunks of trees to prevent injury by rabbits, mice, borers, etc. In order to determine whether this treatment has any injurious effects on the tree, several young apple, pear, and peach trees were painted in the fall of 1903. The paint used was pure white lead, thinned with raw linseed oil. The soil was removed down to the roots and the paint applied on the trunk from the roots to 18 in. above the ground. No injury whatever followed the use of this paint.

The work in regard to the special pruning of fruit trees was carried on as previously outlined (E. S. R., 15, p. 578).

Report of the horticulturist, H. C. HENRICKSEN (*Porto Rico Sta. Rpt. 1906, pp. 18-24, pls. 2*).—The horticultural work conducted at the Porto Rico Station consists mainly of tests as to the adaptability of economic fruits; the introducing and testing of new varieties; the selection of superior native varieties; methods of propagation, planting, and fertilization; experiments in shipping fruits to distant markets; and the distribution of seeds and plants of varieties which have given promising results. A summary is given of results secured with the following plants under investigation: Pineapples, mangoes, avocados, citrus fruits, cacao, and grapes. Several other fruits and plants are noted as to their general behavior.

Of the pineapples, the Ruby, a variety from Jamaica, appears to be the most promising of the less-known kinds tried. The Variegated Lajas, a variety found by the writer near Lajas, produced fruit during the past season. The variegation is in the fruit, as well as in the plant, making it valuable for decorative purposes, while the quality is said to be equal to that of the ordinary Cabezona. Attempts have been made for several years to ship the Cabezona pineapple

to the States. These generally proved unsuccessful, apparently because of rough handling, bad packing, and wet seasons. In 1906 the season was favorable for shipping, and experiments were continued. Of shipments made to New York, a very small percentage of the fruit was spoiled. Shipments to Boston and Washington were reported as having been received in perfect condition. A special crate has been made for the Cabezona, which measures 16 in. wide, 14 in. deep, and 30 in. long, holding 8 pines weighing from 6 to 12 lbs. each. In harvesting the Cabezona a portion of the stem must be cut off with the pine, since when the pine is removed from the stem, as is done with the Red Spanish, a cavity is left in the end of the fruit in which decay rapidly starts.

Experiments were made in dipping the fruit in solutions like ammoniacal copper carbonate and a weak formalin solution, as well as dipping the ends of the stems in melted paraffin, which, however, appeared to be of no benefit.

Over 100 varieties of citrus fruits are being tested at the station, and some very desirable local varieties have been found. An entirely seedless orange, found near Mayaguez, is said to be very promising, and a perfect navel, also entirely seedless, was found near Penuelas and budded at the station under the name of Penuelas Navel. Extensive fertilizer experiments with citrus fruits are being conducted in cooperation with planters.

Several varieties of cacao imported from Trinidad and planted in 1903 are now fruiting, but the fruit is seriously attacked by the pod disease. Investigations are to be made to determine if picking and burning the diseased pods and spraying can be done with profit.

Some Early Harvest and Red Astrachan apple trees planted in April, 1905, bore fruit during the past season of fair quality and not the least diseased. Peaches of the Peen-To, Jewel, and Waldo varieties, planted at the same time, have also produced fruit of first-class quality.

About 1,000 packages of seed and plants have been distributed to planters on the island and to various points in the United States and abroad.

Vegetable growing in Porto Rico, H. C. HENRICKSEN (*Porto Rico Sta. Bul.* 7, pp. 64, pls. 10, figs. 2).—This is the Spanish edition of this bulletin, the English edition having been previously noted (E. S. R., 18, p. 142).

The use of manure as a summer mulch in vegetable forcing houses, W. J. GREEN and C. W. WAID (*Ohio Sta. Circ.* 69, pp. 4).—In this circular an account is given of an experiment conducted at the Ohio Station during the past 2 seasons on the use of strawy manure on the soil as a mulch during that part of the summer when crops are not growing in the greenhouses.

The crops tested were tomatoes and lettuce. The soil was mulched to a depth of 5 or 6 in. with fresh strawy manure, and water applied in the form of a spray until the manure and soil were thoroughly wet. Watering was repeated often enough to keep the soil moist. At planting time the coarse part of the manure was removed and the finer portion was worked into the soil; soil mulched in this manner was found to be in good mechanical condition and darker in color than unmulched soil. On the lettuce plats 3 successive crops were raised without the application of any additional manure or fertilizer. Liquid manure was furnished the tomato plants when the fruit began to ripen. This method of treating the soil gave very favorable results at the station.

Similar experiments were also conducted by the Miller Bros. of Toledo, Ohio, in the past 2 seasons unknown to the station authorities. As a result of the two series of experiments the station recommends this mulching for soils which are to be used for vegetable forcing. The manure should be sufficient in quantity and richness to furnish enough plant food when leached into the soil to supply 3 crops of lettuce, and should be applied to a depth of at least 5 or 6 in. A considerable quantity of coarse material in the manure is said to be an advan-

tage. Where it is the practice to mulch the cucumber or tomato crop, the manure used for that purpose can be left on and more added in cases where the cucumbers or tomatoes have been free from disease. Otherwise the mulch should be removed and new applied. Frequent sprinkling of the manure on the beds is considered very essential in order to cause the richness to leach into the soil.

In a discussion of the bad practice of allowing the soils to dry out during the summer, the authors quote from Stone and Smith (*E. S. R.*, 14, p. 157), to the effect that in drying out of the soil the activity of the *Sclerotinia* or Drop fungus is apt to be accelerated, which largely increases the amount of infection in the succeeding crop of lettuce. The other injurious effects in drying out the soil are manifested in a stunted growth, and abnormally colored and worthless crops.

In the mulching experiments conducted by the Ohio Station and Miller Bros., although no attempt was made to study the effect of mulching on diseases affecting lettuce, the crops are reported as having been practically exempt from these diseases.

Greenhouse experiments for 1906, J. G. MOORE (*Wisconsin Sta. Rpt. 1906, pp. 221-226*).—A preliminary report of experiments conducted at the greenhouse in 1906. In addition to experiments to determine the influence of excessive feeding of plants, a variety test with radishes and 3 experiments with tomatoes, lettuce, and cucumbers were conducted in the greenhouses during the past year.

The experiment with tomatoes was to determine the relative earliness of fruiting and the amount of fruit produced by plants grown from cuttings and those grown from seed. The results thus far indicate that it is very hard to choose between cuttings and seedlings for use in the forcing-house.

Experiments were conducted with lettuce to determine the advantages of the relative value of subirrigation as compared with surface watering. The experiment is discussed at length. Two crops of lettuce were grown. The first crop was harvested from January 15 to 31 and the second crop from April 2 to April 7. In summing up the results from both crops it was found that the surface-watered bench yielded nearly 60 lbs. more lettuce than did the subirrigated bench, or a difference of approximately 600 lbs. for a house 20 by 100 ft. Judging from these results the author is of the opinion that with proper care as large crops can be produced with surface watering as with subirrigation, and that the added precaution necessary in surface watering is more than offset by the difficulties and cost connected with the subirrigation system. The relative effect of these 2 methods of watering on the control of rot has not yet been sufficiently studied to warrant a statement.

An experiment is being conducted to determine the value of super-heated soil or bottom heat in the forcing of cucumbers.

A test of varieties of tomatoes, and further notes and experiments with western blight or yellows, L. F. HENDERSON (*Idaho Sta. Rpt. 1906, pp. 14-28*).—A variety test with tomatoes commenced by L. B. Judson was completed by the author. A chart is given showing the varieties used, with notes in each case as to whether the vines were pinched or unpinched, and the fertilizer used, if any. The test included 53 rows with 95 plants to the row. Data are also given showing the number and weight of sound and the number of rotten tomatoes gathered from each row at the time of the first picking, and the average for the 3 pickings.

The results of fertilizer experiments are tabulated, and the following deductions are drawn: Plants treated either with nitrate of soda or in most cases with sulphate of iron gained nothing the first year in earliness over

those untreated, whether pinched or unpinched, nor in total production of fruit for the 3 pickings. The number of rotten tomatoes was greater where sulphate of iron was used. In every case the unpinched plants gained in earliness over those pinched. The apparent lack of results from the use of fertilizers is believed to be due to the fact that the ground was already rich enough in natural food elements.

In general, the results of the experiment are summarized as follows: Fertilizing good ground in Idaho seems unnecessary. Pinched plants grew fewer tomatoes than the unpinched plants. Sparks Earliana outran all others in earliness and amount of yield for 3 pickings, followed by Nolte Earliest, Maule Earliest, and Mikado. Lists are given of tomatoes desirable as to their solidity, smoothness combined with solidity, and resistance to frost.

The experiments for western blight as noted (E. S. R., 17, p. 1076) were continued, particular attention being paid to water, manures, and shading from sun and wind. The results are given, together with the notes of other tomato growers in regard to blight. On the evidence secured, the author is of the opinion that good plants set in good soil, well watered, and above all protected from the hot sun and heavy winds, will not blight very much.

Celery, W. R. BEATTIE (*U. S. Dept. Agr., Farmers' Bul. 282, pp. 36, figs. 16*).—This is a revision and extension of Farmers' Bulletin 148 (E. S. R., 13, p. 1045), and is intended to take the place of that bulletin.

Popular directions are given for the culture of celery, in which the various phases of the industry are considered, including a discussion of the climate, soils, fertilizers, sowing, planting, cultural methods, diseases, insect enemies and their control, methods of blanching, storing, marketing, and estimates as to the cost of production and returns. The text is accompanied by many illustrations, and the bulletin concludes with lists of varieties recommended for planting for home use and for market.

The best way to grow celery, W. H. JENKINS (*Farming, 3 (1907), No. 4, pp. 136, 137, figs. 6*).—Popular directions are given for the intensive cultivation of celery, in which all phases of the subject are considered, including varieties recommended for planting and culture under irrigation methods. A homemade celery planter is described and illustrated, which is said to mark the rows, make holes for the plants, and supply water for 2 rows at a time as fast as a man walks. The cost of growing celery according to the intensive plan is estimated as \$460 per acre, and the gross receipts as \$1,000 per acre, making a profit of \$540 per acre.

Cranberry investigations, A. R. WHITSON, O. G. MALDE, and C. B. HARDENBERG (*Wisconsin Sta. Rpt. 1906, pp. 135-159, figs. 3*).—The present investigations have corroborated many results obtained from previous work (E. S. R., 18, p. 239). Further information is given on the influence of drainage, sanding, and weeding on soil temperatures, on cultural methods and insect enemies, and on methods of preventing injury by worms. A collection of all the small moths found on cranberry marshes has been started in order to enable the grower to distinguish between the injurious and noninjurious species. A list is given of the moths which have been identified, together with notes on the injury done by various worms.

Observations of soil temperatures at 3 and 6 in. below the surface and of air temperatures at 2 in., 3 ft., and 40 ft. above the surface were made at 7 o'clock both morning and evening during the months of August and September and are here tabulated. Attention is called to the great difference in minimum temperature on nights when the temperature gets low on account of excessive radiation, between plats which are relatively free from weeds and have a surface sanding

and those which are weedy and poorly drained, it being much lower in the latter case.

The importance of keeping cranberry grounds as free as possible from weeds and pruning the vines is again brought to the attention of the growers as one method of lessening the danger from frost. The minimum temperatures taken from May 9 to Sept. 30 in the vines 2 in. above the surface of the ground and in the air 3 ft. above the ground are tabulated. From this data it is shown that the low temperatures and formation of frost locally are largely the results of radiation, and that under conditions favorable for this process the temperatures in the vines go much below that of the air a short distance above.

A 3 years' summary is given of 3 plats which were drained to a depth of 14 in., of 4 to 8 in., and with water at the surface, respectively. The average yield for the 3 years is slightly in favor of the plat drained to a depth of 14 in., and the results appear to be in favor of thorough drainage, the benefits derived being attributed to the warmer average temperature of the drained soil.

The observations of 1905 on the relation of the humidity of the atmosphere at 7 p. m. to the minimum temperature of the night have been repeated during 1906, from May 19 to September 30, and are presented in tabular form, in which it is shown that the temperature of the night frequently went 20° below the dew point of the evening, and in one case 26.2° below the dew point at 7 p. m. The fall of the temperature below the dew point on clear nights was accompanied by excessive dew.

Sanding the plats appeared to increase the yield and also made an increase in uprights by covering a multitude of runners and allowing them to root, thus invigorating the whole plant. In the fertilizer tests the application of nitrate and phosphate gave the best results, as in previous experiments.

An experiment was conducted to determine whether the removal of moss and other forms of vegetation from vines before planting lessens the growth, either by injuring the vine or by removing matter which would otherwise act as a mulch. Thus far the results seem to be in favor of cleaning the vine.

In an experiment carried on to determine the advantage of covering a portion of the vines with muck as they are planted in comparison with planting in the usual way by tamping, no difference was noted in favor of covering with muck. On the other hand, much additional weed seed was added to the plats by the muck.

With reference to the value of planting cut and uncut vines, the growth was found to be practically the same in both cases. Comparisons were made of propagation by cuttings and from seed, the former being the usual method. The results of these comparisons are given in a table and show a great uniformity of parent and seedling in respect to color, size, and shape.

With respect to the effect of flooding on the fruit, the conclusion has been deduced that while cranberries will stand a long flooding where the water is of a low temperature, the use of water above 65° must be of shorter duration.

In a comparison of spraying, flooding, and the use of kerosene for preventing injury by worms, spraying with arsenates has been found an effective means of keeping the insects in check, both as a preventive and as a remedy. Spraying should commence not later than July 1 to obtain the best results and be followed by 1 or 2 further applications at intervals of from 10 to 14 days. Flooding as a remedy for fruit-worm is not to be relied upon under the temperature conditions prevailing on the open marshes of Wisconsin during the period when it would be most effective, unless water of a sufficiently low temperature can be obtained, in which case it is stated that there is no remedy that is more effective and more easily applied than a submersion of the vines, which should continue at least 2 nights and 1 day. A short flooding, sufficient to bring the worm out

of its retreat, followed by the application of a contact poison as soon as the water is removed, is said to be a treatment well suited to Wisconsin conditions. Experiments with kerosene for this purpose and the use of torches have not proven satisfactory thus far.

The importance of clean culture is strongly emphasized for the destruction of favorable hibernating places for insect pests. Both fruit-worms and black-headed vine worms were found to be attacked by a special parasite, the species of which has not yet been determined. The percentage of the affected individuals is not large and the parasite can not be relied upon to keep the worms in check.

The possibilities for fruit growing in Lake Superior region, E. P. SANDSTEN and E. J. DELWICHTÉ (*Wisconsin Sta. Rpt. 1906, p. 230*).—Investigations have been made to study the possibilities for fruit growing on Bayfield Peninsula and at other points in the Lake Superior region. It is believed that Bayfield Peninsula, through its favorable location, will in the near future produce apples and cherries sufficient to supply the immediate wants of nearby markets. To encourage fruit growing in this region, and to study the adaptability of the various varieties, trial orchards have been established at several points.

Orchard fruits, E. P. SANDSTEN (*Wisconsin Sta. Rpt. 1906, pp. 219, 220*).—An outline is given of the fruit investigations at the station.

In the work of improving the native plum, started about 12 years ago by the late E. S. Goff, out of a total of 50,000 seedlings grown from standard varieties some 5 or 6 superior varieties have been selected and are now being propagated. The author states that as a result of the work it is shown that the native plum comes true, or nearly true, from seed in spite of the fact that the parent trees, from which seed has been gathered have grown close together and have been freely exposed to cross-pollination. It is the author's opinion that any difference between the seedlings and the parent trees can be accounted for largely by the difference of soil and cultural methods. The experiments seem to indicate that high culture and persistent selection will accomplish more for the native plum than direct crossing between the existing native varieties. During the past 3 years a number of attempts have been made to cross the native plum and the Japan and European varieties, the results being unsatisfactory since in every instance where crosses were secured the seed failed to grow.

Most of the seedlings in the experimental work in the apple orchard fruited during the year and several very promising varieties were grown.

In order to give general advice in regard to small fruits, most of the leading varieties of gooseberries, currants, and strawberries have been planted, of which records will be kept and data obtained for future reference.

Ampelography, G. MOLON (*Ampelografia, Milan: Ulrico Hoepli, 1906, vols. 1, pp. XLIV + 640, figs. 45; 2, pp. 641-1243, figs. 80*).—A compilation of scientific knowledge on the grape, with descriptions of the better varieties of grapes and practical notes with respect to their cultivation for wine and table use, and their value as graft-stocks and direct bearers.

The work is divided into 7 parts. In part 1 is assembled the available botanical knowledge with reference to the Ampelidæ (Vitaceæ). Succeeding portions of the book are devoted to the various ampelographic classifications, bibliography, and descriptions, together with a large number of practical notes on varieties of grapes. The work closes with a list of synonyms and tables showing the varieties best adapted to different purposes.

Report of the coffee expert, J. W. VAN LEENHOFF (*Porto Rico Sta. Rpt. 1906, pp. 29-31, pl. 1*).—An improved condition in regard to production is reported among the coffee growers of the island, although little progress has been attained in influencing the American taste to a liking for Porto Rican coffee.

The work on the experimental tracts has been confined chiefly to the care of the plantings made in accordance with experiments outlined in previous reports (E. S. R., 16, p. 144; 17, p. 351). In addition, grafting has commenced in the new coffee plantings, together with fertilizer experiments in both the old and new plantings. A great number of the best varieties of coffee in various countries have been brought together for the purpose of selecting for planting those which bring the highest prices in the markets of the world. Inferior varieties are to be discarded and an attempt will be made to distribute the promising varieties as rapidly as possible among the planters.

In the hope of obtaining a better yield, the station is conducting a series of experiments in fertilizing coffee trees. Coffee is said to bloom in Porto Rico at different periods, according to the altitude and locality. The blooming period on the experiment station tract ranges from February to May, consisting of 1 principal blossoming followed by 1 or more smaller blossomings. The berries ripen about 7 months after the blooming period. Harvesting begins in September and lasts until January, during which time about 10 pickings are made at intervals.

With a view of determining how long wet coffee can be kept without damage to quality and also to determine if the sprouting process influences the flavor, the following experiment was made: On December 30, 1905, a quantity of fermented and recently washed coffee in the parchment skin was put in a heap on a cement floor in a basement resembling a malt cellar. The heap was turned daily. During the sprouting process and before turning, the upper layer, having become dry, was sprayed with water of ordinary temperature. As soon as sprouts of the length of the berry had developed these grains were taken out and dried. By January 23, 1906, the first grains began to sprout, and a month later all the grains had sprouted. The bulk of the coffee was then dried in the ordinary way and hulled. This coffee was submitted to different consumers, roasters, and dealers in the United States, and was generally pronounced to be of good quality and flavor. By some the flavor was claimed to have been improved by the sprouting process.

FORESTRY.

The Forest Service of the United States, O. W. PRICE (*Canad. Forestry Jour.*, 3 (1907), No. 1, pp. 14-18, pl. 1).—An outline of the essential progress made by the United States Forest Service along the main lines of forest work.

Report of forest nurseryman, D. HAUGHS (*Rpt. Bd. Comrs. Agr. and Forestry Hawaii*, 3 (1906), pp. 67-83).—A report of the work at the government nursery, the Nuuanu station, and the Tantalus forest for the year ending December 31, 1906.

Statements are given of seeds and plants collected, propagated, and distributed, of plantations visited—showing the nature of the advice and assistance given to those outside of the district of Honolulu—the experimental work, and the number of fires during the year.

The experimental work at the nursery has been along the lines of seed testing and the propagation of new and rare plants, in which various forms of rubber trees have been given considerable attention.

State nursery for forest tree seedlings, L. R. JONES (*Vermont Sta. Bul.* 127, pp. 43-52).—The Vermont general assembly of 1906 passed an act to aid in the establishment and maintenance of a nursery for forest seedlings at the Vermont Station. The various sections included under this act are given in the bulletin.

Under section 3, the law requires that the experiment station shall, as soon

as possible, furnish to all applicants who are residents or landowners of Vermont, material for forest planting as near actual cost as possible. The station here offers an assortment of 4 different classes of white-pine seedlings for forest and nursery growing, together with a few black locust trees, and gives advice to prospective buyers in regard to which class of trees to buy, together with notes relative to forestry planting, the kind of trees to plant in Vermont, the time and method of planting, transplanting native seedlings, seed collecting and sowing, and making nursery beds. A detailed discussion of forest planting in Vermont has been previously noted (E. S. R., 17, p. 1074).

Report of district foresters (*Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 3 (1906), pp. 84-118*).—This report consists of brief statements of several of the district foresters of the Territory of Hawaii as to the present extent and condition of the native forests, the extent of private forest reserves, the area of forest land exempt from taxation, and the forest plantings for the year, together with general notes on forestry.

Forest management in southern pines, M. ROTIKUGEL (*Forestry Quart., 5 (1907), No. 1, pp. 1-10*).—The author was employed for some time as forester for a large lumber company near Charleston, S. C., and gives a description of the system of fire protection adopted by that company, together with notes on the management of loblolly and longleaf pine areas for the purpose of obtaining a constant supply of lumber.

Report of the controller, experiment station, Peradeniya, H. WRIGHT (*Circs. and Agr. Jour. Roy. Bot. Gard. Ceylon, 3 (1906), No. 24, pp. 301-339*).—This is a tabulated report of experiments commenced or continued at the station during 1905 with cacao, rubber, tea, citronella grass, lemon grass, and groundnuts. An enumeration is also given of 146 one-acre plots, showing the present plantings of cacao, coffee, cinnamon, annatto, croton, areca nut, coconut, pomelo, teak, different species of rubber, and several other varieties of important trees. Since the first report of 1903 (E. S. R., 16, p. 265) the plantings of various trees have increased from 38,231 to 83,163 in 1905.

The work with cacao consisted in the excision of cankers and experiments in spraying and fertilizing, and the results, together with notes on the progress and composition of the crop, flower periodicity, and returns from plots, are presented in tabular form. Results are given of yields secured from some of the rubber trees, showing the date of each tapping, the amount of rubber obtained, and the total amount of rubber obtained for the season. Four Peradeniya trees, 29 years old, produced from V-shaped cuts a total of 11 lbs. 5 $\frac{3}{4}$ oz., and 4 similar trees yielded from long spiral cuts a total of 17 lbs. 8 $\frac{3}{4}$ oz. for the season.

Treatment of cooperative forestry plats (*Ohio Sta. Circ. 68, pp. 4, fig. 1*).—This circular contains advice on the pruning of forest trees at planting and in the nursery. The locust, catalpa, mulberry, and osage orange are discussed somewhat in detail.

Experience thus far has shown that if, before planting, the tops are cut off 1 or 2 in. above the point where the top and root join, the result is better than if the cut is made several inches higher, since but one sprout usually starts where the cut is made low down, and a clean, vigorous growth is assured. This treatment is advised for all young forest trees except evergreens. The practice of allowing catalpa trees to grow 2 or 3 years before pruning is not to be recommended, since although a long stem is usually secured it is apt to become top-heavy and easily damaged by the wind when the foliage is wet. The better plan is to keep the trees growing straight from the start. In cases of crooked trees, or where severe injury has been caused by mice or rabbits, the trees should be cut to the ground regardless of their age.

It has been found that trees grow much faster under cultivation than when in

sod. The cultivation of locust trees for more than one season is of doubtful utility, since if the roots are lacerated sprouts will spring up. Banking the trees with a few shovelfuls of earth each fall lessens the risk of the trees being gnawed by mice.

The importance of climatic varieties of species of trees for silviculture, A. CIESLAR (*Centbl. Gesam. Forstw.*, 33 (1907), Nos. 1, pp. 1-19; 2, pp. 49-62, figs. 8).—An account is given of investigations made by the author and others on the adaptability of species of trees grown in high altitudes for planting in low-land countries, and vice versa. The principal trees discussed are the spruce, larch, white and black pine, and sycamore.

As a result of these investigations the author concludes that in the reforestation of any area trees should be used which are native to that particular climate.

Table for determining the financial increment per cent of trees based on their market values, N. B. ECKBO (*Forestry Quart.*, 5 (1907), No. 1, pp. 37-39).—This table, prepared by E. Overland, forest estimator in the Norwegian government service, is explained in detail and is said to be of the same value in uneven-aged stands as in even-aged, since the rate of increase of each diameter class is determined separately.

New method of measuring volumes of conifers, B. E. FERNOW (*Forestry Quart.*, 5 (1907), No. 1, pp. 29-36).—The author states that the most important development in mensuration in later years is the substitution of the "form quotient"—as elaborated (after Schuberg's proposition) by Schiffel—for the "form factor." As a result of further investigations made at the Austrian experiment station, Schiffel reports that "all conifers (the European fir, spruce, pine, larch) can be approximately but sufficiently accurately cubed upon the basis of one and the same form quotient table."

The author gives a brief explanation of Schiffel's method, together with formulas and tables used.

The influence of light and of changing temperatures on the germination of seeds of cultivated plants, especially pine, A. ATTERBERG (*K. Landtbr. Akad. Handl. och Tidskr.*, 45 (1906), No. 3-4, pp. 299-315).—A review of the literature on this subject is given, together with a report on experiments along this line. It was noted that variation in temperature does not equal the beneficial effect of light in the germination of pine and many other kinds of seed.

The best methods of germinating the seeds of different agricultural crops are discussed.—F. W. WOLL.

Observations on the effects of spring and autumn frosts in 1905-1906, H. J. ELWES (*Quart. Jour. Forestry*, 1 (1907), No. 2, pp. 169-179).—Notes are given as to the effect of frost on a large number of hardwoods, conifers, and shrubs during the spring and autumn periods of 1905 and 1906.

India rubber on the island of Cuba, H. C. PEARSON (*India Rubber World*, 36 (1907), No. 2, pp. 237-242, figs. 14).—An illustrated account of a large number of species of both exotic and native rubber-producing plants found in Cuba, with suggestions as to the value of the different species.

Present and future phases of the India rubber industry, TOBLER (*Sitzber. Naturhist. Ver. Preuss. Rheinlande u. Westfalens*, 1906, I, pt. C, pp. 7-9).—This is a brief report of a lecture delivered by the author on the various phases of the rubber industry, in which mention is made of the synthetic production of caoutchouc by Harries from the residue obtained in the manufacture of sugar. Reference is also made to the various families of rubber-producing plants.

The cocoanut palm in Ceylon, J. FERGUSON (*Jour. Ceylon Branch Roy. Asiatic Soc.*, 19 (1906), No. 57, pp. 39-70, map 1).—This is a paper on the beginning, rise, and progress of cocoanut cultivation in Ceylon from earliest times to 1660, the close of the Portuguese occupation of the maritime provinces,

in which the author refers to a great number of early writers on the subject. At the beginning of the last century it was estimated that there were 10,000,000 cocoanut palms in Ceylon. The author intends to cover the Dutch and British periods in a later paper.

A map is given showing the location of the early cocoanut plantations in Ceylon.

The Tavistock woods, W. SCHLICH (*Quart. Jour. Forestry*, 1 (1907), No. 2, pp. 156-167).—This is an account of sylvicultural work which has been conducted in the Tavistock woods, the property of the Duke of Bedford, during the last 8 or 9 years. A general description of the forest growth, the plans for the management of the woods as laid down by the author in 1898, and a summary of the work actually carried out are given. The plans include the treatment of oak timber areas, mixed woods, simple coppice woods, and standels.

During the past 8 years over 620 acres have been stocked with various species of hardwoods and conifers.

Evergreens for the Iowa planter, A. T. ERWIN and H. P. BAKER (*Iowa Sta. Bul.* 90, pp. 46, figs. 16).—Early in the seventies the horticultural section of the Iowa experiment station instituted an extensive experiment in the testing of new species of evergreens to determine their hardiness and value for Iowa conditions. This work has been continued from year to year and this bulletin is the first report of these investigations.

A record is given of the behavior of the more important species of evergreens tested both at the station and throughout the State generally, together with estimates of their value for the Iowa planter. Part 1 is devoted to a general discussion of tree growing in Iowa, and the transplanting, cultivation, and pruning of evergreens. Part 2 consists of a report on species planted in the State with regard to hardiness, adaptability to various soils, comparative rate of growth, and general value for forestry and ornamental purposes. The groups considered are pines, larches, spruces, hemlocks, firs, cypresses, arbor vitae, junipers, and ginkgos. A list is given of evergreens recommended for planting in different parts of the State under the conditions discussed, and many of the species are illustrated.

Preservation of wood used for telegraph poles, R. NOWOTNY (*Baumaterialienkunde*, 12 (1907), No. 5-6, pp. 65-69).—This is a comparative review of the various methods and materials either used or under experiment for the preservation of telegraph poles both in Europe and the United States.

DISEASES OF PLANTS.

Report of the botanist, H. L. BOLLEY (*North Dakota Sta. Rpt.* 1906, pt. 1, pp. 28-36).—The principal investigations carried on by the botanist have been in the study of resistance to disease in plants. An attempt was made to determine whether resistance to disease is an individual characteristic or whether this resistance is gained by gradual accretions from season to season. Especial attention was given to the possibilities of breeding resistant races of potatoes, flax, and wheat.

In the flax selection experiments the author has found that all cultivated varieties seem subject to wilt disease, but that they are not equally subject to flax rust. In his experiments with the flax rust, and cooperative experiments conducted at the Indiana Station he found that the flax rust passes all its different spore stages upon the cultivated flax. This explains the loss from rust in experimental plats which had been devoted to flax growing for a considerable number of years. The author recommends for farm practice that to

prevent excessive rust infection all rusty flax straw be thoroughly composted or burned and that rotation of crops be followed.

In his work with wheat, 401 different strains were under investigation, and all the plats were given every possible chance to become infested with the common wheat diseases.

An experiment was carried on to determine the effect of soil sterilization, in which the soil to a depth of 14 in. was sterilized and afterwards returned to the plat and seeded to wheat. The yield of straw and grain on the sterilized plat was above the normal growth of any near-by field crop, and the yield the second year after sterilization was more than one-third greater than a similar non-sterilized plat.

A brief account is given of experiments on the fertilization of clover and alfalfa, in which areas of red and white clover and alfalfa were covered with small meshed wire screen to exclude the larger insects. The results showed that alfalfa could partly fill under such conditions, while white clover produced about one-third as much seed under the screen as in the open, and only 1 head of red clover produced any seed.

In continuation of previous experiments, the author reports on tree feeding, stating that his experiments have progressed sufficiently far to permit a statement that formaldehyde, copper sulphate, and iron sulphate, when properly applied, tend to hasten the recovery of apple trees from sun-scald and sour heart, to check the development of apple blight, and may hold the plum-pocket disease in check. The method of applying the solution is fully described in a previous report (E. S. R., 16, p. 131). Brief notes are given on a plant survey of the State, fungus diseases, weed and seed laws, etc.

The wintering of grain rusts, A. H. CHRISTMAN (*Trans. Wis. Acad. Sci., Arts, and Letters, 15 (1904), pt. 1, pp. 98-107*).—The author gives a review of observations made by different investigators on the wintering of cereal rusts. In order to test the ability of rusts to winter as mycelium and uredospores in a latitude farther north than reported by others, he undertook a series of observations on several of the common rusts through the winter of 1902-3.

Well rusted plants could easily be found late in November, and during the winter and early spring material was gathered from rye, wheat, blue grass, and oats, some of the plats being protected by a covering of snow, while others were exposed during a greater part of the winter. Water cultures were made of the uredospores, and the germination of the spores as well as the maximum and minimum temperature of each day are shown in tabular form. Spores were germinated on every day noted except in one instance, where they were collected on February 18. It appears from the table that in the latitude of Wisconsin, and with a period of 3 months during which the temperature scarcely rises above the freezing point, viable uredospores may be obtained at practically any time during the winter.

It was noted early in the winter that in the case of badly rusted grain many of the leaves exhibited pale spotted areas, and sections of these showed the presence of mycelium and undeveloped spores.

Continuing his observations, the author found that in the spring of the year there were 2 distinct outbreaks of rust, the first occurring on the old winter leaves within 2 weeks following the first warm weather, while the second crop of uredospores did not appear until after the development of the first spring leaves. He found by experiment that in the cool weather of the spring the incubation period following inoculation is usually lengthened to between 3 and 4 weeks. The winter leaves die early in the spring and with them the winter mycelium, but not until it has produced uredospores which inoculate the new leaves. Between the dying of the old leaves and the appearance of rust on the

new a period of incubation takes place, which may be lengthened more or less according to the temperature and other conditions in the spring.

In conclusion the author says that as the severity of the winter must affect the amount of healthy host tissue that survives the winter, it must also limit the amount of mycelium and the number of uredospores in the spring, and that this in all probability is one of the chief factors in determining the violence of early outbreaks of rust.

Treating seed grains for the prevention of smut, R. A. MOORE and A. L. STONE (*Wisconsin Sta. Rpt. 1906*, pp. 270-274, fig. 1, dgm. 1).—Experiments were carried on by the authors to lessen the loss caused by smut diseases of barley. The treatments included soaking the seed grain in formaldehyde and corrosive sublimate solutions, and a modified form of the hot-water treatment.

The formaldehyde and corrosive sublimate treatments were effective in controlling the form of smut known as closed smut, but they were without effect for the loose smut of barley. For this the authors recommend soaking the seed grain for 12 hours in cold water, after which it is submerged for from 5 to 20 minutes in water at a temperature of 130° F. As this treatment is efficient for both forms of smut, it is recommended for combating smut diseases of barley.

A contribution to the biology of ergots, R. STÄGER (*Centbl. Bakt. [etc.]*, 2. Abt., 17 (1907), No. 22-24, pp. 773-784).—Inoculation experiments were carried on for 2 years with conidia and sclerotia of *Claviceps* on *Sesleria carulea* from different localities to determine the possibility of biological races of this species. A considerable number of species of grasses were inoculated, but on only a few were the inoculations successful. The results obtained show the apparent identity of the ergot from 2 localities, the differences attributed being due to climatic conditions. Based upon his experiments the author gives an amended description of the biological race occurring on *S. carulea*.

Infection experiments with Erysiphe graminis, G. M. REED (*Trans. Wis. Acad. Sci., Arts, and Letters*, 15 (1904), pt. 1, pp. 135-162).—The author conducted a series of inoculation experiments, using the conidia of *E. graminis* from blue grass and rye, and as host plants rye, wheat, oats, barley, squirrel tail barley, smooth brome grass, various species of *Poa*, rye grass, tall meadow fescue, orchard grass, timothy, floating manna grass, etc.

In the experiments with conidia from blue grass it was found that the mildew on *Poa pratensis* will not readily infect the other species of *Poa* experimented with. Under certain conditions it seems to be able to pass over to some extent to *P. nemoralis* and in a still less degree to *P. trivialis* and *P. compressa*. In the experiments with conidia from rye no inoculations were successful except on the control rye plants. In all the experiments the seedlings of rye which were inoculated with conidia from rye uniformly became infected, and this was also true when blue grass was inoculated with conidia from blue grass. When inoculations were made on other host plants in nearly every instance there was no infection.

The experiments confirm the general conclusion that spores of the mildew from one grass will not infect a grass belonging to a different genus. It seems probable that for *E. graminis* at least there is one if not more distinct species for each genus of grasses, and in some instances there may be a number of physiological forms upon the various species of the same genus.

Further researches on brusone of rice in 1905, U. BRIZI (*Ann. Ist. Agr. [Milan]*, 6 (1901-1905), pp. 61-103, figs. 6).—The experiments previously carried on by the author had indicated that brusone may be caused by physiological conditions. In the experiments upon which the present article is based, this problem was tested on a larger scale with 3 varieties of rice, which showed considerable differences in their resisting power toward unfavorable conditions

about the roots. When the usual supply of oxygen was withheld from the roots, yellowish, reddish, or brownish spots appeared on the leaves and other aerial portions of the stem within a few days. It was also observed that *Piricularia oryzae* developed and fruited in some of these spots.

In control plants, however, kept under proper conditions for growth, it was found impossible to produce an infection with this fungus in a single case. These experiments are held to confirm results previously obtained and indicate that brusone is due to a deficiency or absence of free oxygen in the vicinity of the delicate absorbing rootlets. According to the author, practical rice growers have found that there is more danger of brusone when the rice is dry in the morning than when it is moistened with dew. These facts would be difficult to explain if the disease were due to a fungus.

While the author does not claim to have demonstrated beyond question the cause of brusone, he believes that it is probably due to the irregular or incomplete respiration of the minute absorbing rootlets still without a cork layer.

The winter rot of potatoes (*Jour. Bd. Agr. [London], 13 (1907), No. 12, pp. 739, 740, fig. 1*).—A description is given of a rot of potatoes in cellars and storage pits which is due to the fungus *Nectria solani*. For the prevention of this rot the writer suggests that potatoes should be well dried before storing and sprinkled with powdered sulphur during the process of drying. Land that has produced a diseased crop will certainly be infected with the fungus and should not be planted to potatoes again for several years. The use of lime or kainit is recommended on infected land.

Potato spraying experiment, E. P. SANDSTEN and J. G. MILWARD (*Wisconsin Sta. Rpt. 1906, pp. 209-218, figs. 3*).—In order to determine the actual cost under ordinary farm conditions spraying experiments have been carried on for the past 3 years in the principal potato-growing counties of the State. A detailed account of these experiments is given in a previous publication of the station (*E. S. R., 18, p. 53*). In 1905 experiments were conducted on 3 areas of 30 acres each in which 5 applications of Bordeaux mixture were sprayed at a cost of \$3.70 per acre, the net gain ranging from \$15.50 to \$36 per acre. In 1906 another series of experiments was carried on in which the average gains on 4 fields are expressed in yield per acre, the increases with 6 applications being 18.9, 40, 47, and 29 bu. per acre, respectively.

Pineapple and banana diseases, W. V. TOWER (*Porto Rico Sta. Rpt. 1906, p. 27*).—The author reports a serious trouble of pineapples following the planting of the crowns of the fruit. The plants rotted soon after being set, the first indication of disease appearing in the rotting of the lower leaves and underground parts, and later extending to the center leaves. The exact nature of the trouble has not been determined, but it was found that drying the crowns for 8 or 10 days before planting materially reduced the losses.

The disease of bananas briefly described is believed to be of bacterial origin and is characterized by the darkened areas found throughout the pseudotrunk of the plants. The affected portions of the plants have a very disagreeable odor. From the author's observations it is believed that much damage may result from this disease. A similar disease is said to have been reported in the Leeward Islands.

A disease of coffee, J. W. VAN LEENHOFF (*Porto Rico Sta. Rpt. 1906, p. 32*).—The author briefly describes a fungus disease which attacks coffee berries, the fungus apparently passing through the parchment and causing warty excrescences to appear on the grain. The disease was found to occur on trees grown in shade as well as on those without shade, but perfectly healthy trees were not observed to be affected. An examination of fresh berries indicated that the cause was probably *Stilbum flavidum*. Trees sprayed 3 times with Bordeaux

mixture at intervals of 2 weeks after the falling of the blossoms showed no disease during the succeeding season.

A bacterial disease of fruit trees, R. ADERHOLD (*Deut. Obstbau Ztg.*, 1907, No. 6, pp. 90-94, figs. 2).—An account is given of a bacterial disease of cherry trees due to *Bacillus spungiosus*, which has been previously described (E. S. R., 17, p. 1165; 18, p. 947).

The distribution of the gooseberry mildew in Europe, W. HERTER (*Centbl. Bakt. [etc.]*, 2. Abl., 17 (1907), No. 22-24, pp. 764-773, figs. 3).—The author traces the distribution of the gooseberry mildew (*Sphaerolobea mors-ura*) in Europe for the year 1906, giving the reported stations where it has been observed in Ireland, Russia, Sweden, Denmark, Germany, Finland, Norway, and Austria-Hungary.

A new disease of cacao (*Agr. News [Barbados]*, 6 (1907), No. 128, p. 93).—The writer states that diseased roots and stems of cacao were received from the botanic gardens at Trinidad in October, 1906, which upon examination were found to be infested with dark mycelial threads in the vessels of the roots and with hyphæ of other fungi in the medullary rays and other cells of the stem. The mycelium in the stem appeared to be continuous with black fruiting bodies, which are recognized as species of *Lasiodiplodia*.

Specimens of the stems submitted to this Department were said to be infested with the same fungus as that previously noted (E. S. R., 18, p. 452) as occurring on cacao and mangoes. The identity of the fungus in the roots has not yet been determined.

Attention is called to the presence of this fungus on cacao and other plants in widely distant regions in the West Indies. When the disease is found, all infested twigs and branches should be cut out and burned and dead trees should be uprooted and destroyed.

Diseases of cocoanut palms, F. A. STOCKDALE (*Agr. News [Barbados]*, 6 (1907), No. 127, p. 75).—Descriptions are given of 3 diseases of the cocoanut palms observed by the author in Trinidad.

The first of these, a root disease, is attributed to the fungus *Botryodiplodia* sp., and may be recognized by the yellowing and hanging down of the leaves, by the disorganized condition of the cortex of the roots and the red discoloration in the stem, and by the pustules bearing fungus spores on the dead leaf stalks. This disease may be spread through the soil or by spores. It appears in all soils, but apparently spreads more rapidly and is more destructive in damp, lowlying, undrained regions. To prevent the spread of the disease the author recommends the burning of all diseased trees and rubbish, isolation by digging trenches around diseased trees, cultivation of the land, and spraying with fungicides for the destruction of the spores, as well as applications to the soil for the destruction of the mycelium. Where replanting is necessary it should be done with ripe nuts from disease-resistant trees.

The leaf disease described is caused by a species of *Pestalozzia*, and may be recognized by yellowish spots on the leaflets, especially near their tips. These spots increase in size, the leaf turns yellow, then brown, and finally dies. When the leaflets of the terminal 2 or 3 ft. of the leaves have died this portion breaks off and hangs vertically downward from the end of the dying leaves. This is said to be one of the most characteristic indications of this disease. Associated with this fungus is another, *Diplodia epicocos*, but experiments seem to indicate that it is saprophytic and only completes the destruction begun by the *Pestalozzia*. The spread of this disease is accomplished by wind and rain, and efforts should be made to keep the trees in as healthy and vigorous a condition as possible.

The third disease described is termed bud rot disease, and was noticed in several isolated districts. The cause of the trouble is said to be somewhat obscure. The roots and stem of the palm appear healthy, while the bud is involved in a vile-smelling soft rot. In one instance a fungus was found in the advancing margin of the diseased part, but generally bacteria were the only organisms present. Three different species of bacteria have been observed in connection with this disease, but as yet no definite data have been obtained as to how they gain entrance to the tree or whether they are the primary cause of the disease. It is thought that careful cultivation and the prompt destruction of diseased material would tend to keep this disease in check.

The effect of alkaline polysulphids on spraying apparatus, M. FRÉMONT (*Prog. Agr. et Vit. (Ed. l'Est)*, 28 (1907), No. 11, pp. 329-331).—Attention is called to the fact that in using alkaline polysulphids as fungicides the solutions attack copper lined spraying apparatus. On this account such apparatus should be heavily tin lined to prevent the injurious action of the fungicide.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Inheritance of acquired characters, A. WEISMAN and R. SEMON (*Arch. Russen u. Gesell. Biol.*, 3 (1906), No. 1, pp. 1-27; 4 (1907), No. 1, pp. 1-46).—The controversy set forth in these articles concerns the old problem of whether acquired characters in animals may be inherited, the negative side of the question being taken up by Weisman and the affirmative by Semon. The latter authority maintains that it is impossible to discuss heredity in an unprejudiced manner so long as it is assumed that acquired characters can not be inherited.

The zoological record, D. SHARP (*Zool. Rec.*, 42 (1905), pp. LXV+1201).—As in previous issues of this annual publication elaborate classified bibliographies are given of the literature relating to all branches of zoology. The bibliographies of the various subjects have been worked up by members of the record committee of the council of the zoological society of London. The volume covers the literature published in 1905. It is announced that the volume for 1906 will be a joint production of the international catalogue organization and this committee.

The monthly bulletin of the division of zoology, H. A. SURFACE (*Penn. Dept. Agr., Mo. Bul. Div. Zool.*, 4 (1907), No. 10, pp. 353-382, pls. 2).—Brief recommendations are made regarding the use of carbon bisulphid in combating insect pests of beans, peas, and other seeds; the treatment of San José scale with lime-sulphur wash and commercial insecticides; and the results obtained by commercial orchardists in combating this pest.

Report of the entomologist, C. O. HOUGHTON (*Delaware Sta. Rpt. 1903*, pp. 141-159, pl. 1).—In spraying for San José scale boiled lime-sulphur wash gave better results than the unboiled wash. Pure kerosene did not injure native plum trees, but caused some injury to apple and pear trees. In commercial orchards little difference was seen in the results from the use of boiled and unboiled lime-sulphur washes.

Snowy tree-cricket is reported to have caused injury to the trunk of a plum tree. Brief reports are also made on the Indian-meal moth in jelly, fumigation for the white fly, *Chilocorus similis*, the codling moth, the oyster-shell bark-lice, the mushroom maggot, and the strawberry weevil.

Division of entomology, A. CRAW (*Rpt. Bd. Comrs. Agr. and Forestry Hawaii*, 2 (1905), pp. 99-166, pls. 2, figs. 11).—This material has already been noted from another source (*E. S. R.*, 18, p. 352).

Division of entomology, A. CRAW (*Rpt. Bd. Comrs. Agr. and Forestry Hawaii*, 3 (1906), pp. 139-164, figs. 6).—A summary is presented of the inspec-

tion work which has been carried on by the division in preventing the ravages of insects and fungus diseases in Hawaii. Brief notes are included on insect pests found on shipments of plants which were held in quarantine. Particular attention is given to a discussion of the various importations of beneficial insects which have been made into Hawaii. Recently considerable effort has been devoted to a study of *Eucoila impatiens* and other natural enemies of the horn fly.

Report of the government entomologist, E. E. GREEN (*Circ. and Agr. Jour. Roy. Bot. Gard. Ceylon, 3 (1906), No. 22, pp. 287-294*).—Many of the well-known tea pests continued to give trouble during 1906. The use of sulphur against tea mites has been more extensive. The remedy is effective, but some complaints have been made of injury to the tea foliage from its use.

The cultivation of *Kickxia* rubber has been rendered almost impossible by the attacks of *Caprinia cochylalis*. This pest may be controlled by repeated spraying with arsenicals. Notes are also given on other pests of rubber and cotton.

Attempts are being made to establish apiculture in Ceylon and the government is encouraging the extension of sericulture.

Report of State nursery inspection, J. G. MOORE (*Wisconsin Sta. Rpt. 1906, pp. 231-239*).—Thus far considerable success has been had in keeping dangerous insects and fungus diseases in Wisconsin under control. Notes are given on the prevalence and treatment of oyster-shell bark-lice, cottony maple scale, woolly aphid, peach aphid, imported willow weevil, crown gall, apple blight, etc.

Injurious insects and their control, W. T. CLARKE (*Alabama Col. Sta. Bul. 139, pp. 20*).—Brief mention is made of the kinds of damage which may be done to cultivated crops by insects. Formulas are given for the preparation of Paris green, arsenate of lead, poison baits, and lime-sulphur wash. Attention is also called to the importance of mechanical methods of destroying insect pests and the use of trap crops for this purpose.

Report of the entomologist, C. P. GILLETTE (*Colorado Sta. Rpt. 1906, pp. 142-149*).—During the year under report attention was given to the melon louse, grasshoppers, cottony maple scale, oyster-shell scale, peach-twig borer, peach borer, codling moth, etc. An outline is given of the entomological work proposed for the coming year. The field entomologist, E. P. Taylor, reports on practical work in controlling insect pests, the collection of economic insects, inspection of orchards, and attendance at farmers' institutes. It is stated that despite the excellent spraying equipment in Grand Valley, the codling moth does a great amount of harm. This is attributed to a lack in thoroughness of method, deficiency in spraying material, and incomplete knowledge of the life history of the moth.

Some insects injurious to wheat during 1905-6, L. BRUNER and M. H. SWENK (*Nebraska Sta. Bul. 96, pp. 36, pl. 1, figs. 14*).—In this account of wheat insects particular attention is given to the Hessian fly, which caused a great amount of damage in Nebraska for a number of years, but diminished in numbers when control methods suggested by the station were put into practice by farmers. The habits and life history of the pest are discussed in detail and the standard methods of control are recommended.

Biological and economic notes are also given on the wheat-stem maggot, frit flies, wheat midge, wheat straw-worms, stalk borer, and grain plant louse.

Report of the entomologist and plant pathologist, W. V. TOWER (*Porto Rico Sta. Rpt. 1906, pp. 25-28*).—Some of the orange groves in the island are infested with red scale. A fungus disease has recently been observed to hold this insect in check. One of the most serious pests of the orange is the purple scale, which may be best controlled by the use of lime-sulphur wash. This gives better results than kerosene or crude oil emulsions. Brief notes are also

given on May beetles, orange leaf-weevil, brown scale, and West Indian peach scale.

Attention is being given to the diseases and insect pests of pineapples, bananas, coffee, and sugar cane.

Diseases and insect pests of coffee, J. W. VAN LEENHOFF (*Porto Rico Sta. Rpt. 1906, pp. 31, 32*).—Leaf weevils which commonly live on larger trees around coffee plantations may fall on the coffee trees and feed upon them, causing considerable damage. The coffee leaf-miner was not as abundant as in previous years. Considerable benefit was noted from the thorough fertilization of infested trees.

Bibliography of Canadian entomology, C. J. S. BETHUNE (*Separate from Trans. Roy. Soc. Canada, 2, ser., 12 (1906-7), Sec. IV, pp. 55-65*).—A brief bibliography of works relating to Canadian entomology and published in 1905 is presented in an alphabetical order under the authors' names.

The genus Leucaspis, L. LINDINGER (*Jahrb. Hamburg. Wiss. Anst., 23 (1905), Beiheft 3, pp. 1-60, pls. 7*).—The literature relating to this genus of scale insects is reviewed in connection with a bibliography of 154 titles. The author discusses the general anatomical features of the genus, with suggestions regarding the relationship of different species, and presents an analytical table for the identification of the various species.

The tobacco thrips, a new and destructive enemy of shade-grown tobacco, W. A. HOOKER (*U. S. Dept. Agr., Bur. Ent. Bul. 65, pp. 24, pls. 2, figs. 2*).—In 1904 attention was called to an attack of thrips upon shade-grown tobacco. Other references to injuries of this sort are also noted by the author. The species under discussion in this bulletin is *Euthrips nicotianae*, which is described as new.

The injury caused by this insect is referred to as white vein on account of the color of the veins of infested tobacco leaves. This is quite distinct, however, from white vein of northern grown tobacco, which is due to some physiological disorder.

The insect appears to be distributed rather widely throughout the Southern States and feeds upon a number of weeds and other plants as well as upon tobacco. Only 12 or 13 days are required for a life cycle during warm weather. The insect hibernates in the adult stage.

The tobacco thrips is most successfully controlled by spraying with kerosene emulsion diluted with 10 parts of water and carefully mixed, since free kerosene will burn the tobacco leaves. The application should be made in the evening. Other insecticides were tried with fairly satisfactory results, but were not as effective as the kerosene emulsion. In addition to the use of this insecticide, it is also suggested that the seed bed should be separate from the field in which the tobacco is subsequently planted.

Surface caterpillars, H. M. LEFROY (*Agr. Jour. India, 2 (1907), No. 1, pp. 42-46, pl. 1*).—The term surface caterpillars is used as equivalent to cutworms and notes are given on a number of these pests which attack plantings of opium, peas, and other crops. In combating them, the best success was had from the use of a poison bait containing 4 lbs. of white arsenic and 8 lbs. of sugar in 6 gals. of water which was used to moisten 80 lbs. of chopped straw.

Locusts (*Rhodesian Agr. Jour., 4 (1907), No. 3, pp. 236-247*).—Large quantities of arsenite of soda have been used in attempts to destroy locusts. This application of arsenical poisons led to some complaints that locust birds were thereby destroyed. An investigation of this question showed that very few if any locust-eating birds are destroyed by feeding upon poisoned locusts. A brief summary is given of the discussion held at a recent intercolonial con-

ference in Pretoria for the purpose of arriving at suitable measures for dealing with the locust pest.

The praying mantis, J. R. LINDA (*Com. Par. Agr. [Mexico], Circ. 54, pp. 14, figs. 15*).—The author presents notes on the habits and life history of *Mantis religiosa* and *M. carolina*, with particular reference to the benefits conferred upon agriculture by these insects.

The chief enemies of the apple, E. MARCHAL and POSKIN (*Bul. Agr. [Brussels], 23 (1907), No. 1, pp. 56-90, figs. 38*).—A general review is presented of the insects and fungus diseases which constitute the most important enemies of the apple. Formulas are given for the preparation of suitable insecticides and fungicides.

Orchard and bush fruit pests in 1906, F. V. THEOBALD (*Jour. Bd. Agr. [London], 13 (1907), No. 12, pp. 705-719*).—In certain consignments of imported apples the codling moth was found in considerable numbers. This insect was not as injurious in orchards as during former years. Brief biological and economic notes are given on the pear midge, woolly aphid, hop aphid, various other plant lice affecting currant, gooseberry, strawberry, and apple, oyster-shell bark-louse, etc. During recent years the blackbird has increased greatly and now causes serious damage to bush and orchard fruits.

Mixed sprays for apple scab and codling moth, L. F. HENDERSON (*Idaho Sta. Bul. 55, pp. 27*).—Since apple scab and codling moth are two of the most important enemies of apple orchards it was thought advisable to carry on experiments to determine more satisfactorily certain points regarding the use of mixed sprays combining a fungicide with an insecticide for the control of the two pests by one operation.

It was found that three applications of Bordeaux mixture in ordinary years control apple scab in a satisfactory manner. The use of Bordeaux mixture just when the fruit is setting sometimes causes a russeting of the fruit and it is, therefore, believed that this application of the Bordeaux mixture should be omitted if any. Arsenate of lead, applied three times, gave the best results in the control of codling moth. It was found that the use of bands also assists greatly in the control of this pest.

In connection with thorough spraying it is recommended that apple trees should not be planted closer together than 24 or 25 ft., that thorough cultivation should be adopted, and that a suitable supply of humus and fertilizers should be maintained in the soil.

The apple leaf-miner. A new pest to the apple, C. D. JARVIS (*Connecticut Storrs Sta. Bul. 45, pp. 35-55, figs. 15*).—The apple leaf-miner is well distributed over the eastern part of the United States and Canada, but has not heretofore been regarded as a serious pest of the apple. During the past season, however, it proved in parts of Connecticut to be very injurious to the apple and also fed on the blackberry, haw, raspberry, and other related plants. This insect develops two broods during the season, the second of which is the more important. Hibernation takes place in the caterpillar stage.

The insect is described in all its stages. The larvae produce mines in the substance of the leaves and are sometimes so numerous as to form large discolored blotches. The eggs are deposited early in June.

It appears that orchards in cultivated soils suffer less from this insect than those which are left in sod. The collection and destruction of the fallen leaves in autumn is recommended, since the insect at that time of the year is found in the substance of the leaves. In most localities the pest has not yet proved serious, but wherever it is abundant attention should be given to the destruction of the leaves in the fall in order to prevent its further spread.

Spraying demonstrations in Nebraska apple orchards, R. A. EMERSON (*Nebraska Sta. Bul. 98, pp. 35, figs. 7*).—The spraying demonstrations reported in this bulletin were carried on in 6 commercial orchards and the sprays were applied at 5 periods, viz., April 23 to May 1, May 7 to 17, May 15 to 26, June 6 to 9, and July 10 to 25. The materials used for spraying were Bordeaux mixture and an arsenical (arsenate of lead, green arsenite, or Paris green).

Upon tabulating the results obtained from these experiments it was found that the average cost of spraying was 21 cts. per tree and that a net value of \$1.66 was obtained from the fruit of each sprayed tree as compared with 80 cts. for each unsprayed tree. The returns per acre were about \$80 and \$40, respectively. It is recommended that in Nebraska apple trees be sprayed with Bordeaux mixture just before the flower buds open, with Bordeaux mixture and an arsenical immediately after the blossoms fall and also 3 or 4 weeks later, and with arsenate of lead on July 20 and August 10.

Spraying for apple diseases and the codling moth in the Ozarks, W. M. SCOTT and A. L. QUAINANCE (*U. S. Dept. Agr., Farmers' Bul. 283, pp. 12, figs. 7*).—The treatments planned by the authors were designed to control apple scab, apple blotch, leaf-spot diseases, bitter rot, and codling moth. Applications were made just before the flowers opened, just after the petals fell, 7 days later, after another 3 weeks, and on June 25, July 17, and August 11. Bordeaux mixture with an arsenical added was found to be the most effective treatment for the principal diseases of the fruit and foliage of the apple and also for the codling moth. A good quality of Paris green is satisfactory, and when applied with Bordeaux mixture adheres well to the foliage. Arsenite of lime is the cheapest of all the arsenicals used in these experiments.

With varieties of apples ordinarily immune to scab the first application is not necessary, and in localities where bitter rot does not prevail the last application may be omitted.

Insect and fungus enemies of the grape east of the Rocky Mountains, A. L. QUAINANCE and C. L. SHEAR (*U. S. Dept. Agr., Farmers' Bul. 284, pp. 18, figs. 35*).—The authors, working in cooperation, have devised a treatment which is effective against the grape root-worm, berry moth, curculio, leaf moth, leaf-hopper, leaf-folder, and flea-beetle, the rose chafer, black rot, downy mildew, powdery mildew, anthracnose, ripe rot, bitter rot, white rot, crown gall, and root rot, and against shelling. Brief notes are given on the appearance and life history of these grape pests and on the preparation and application of insecticides and fungicides.

In controlling these pests it is recommended that a first application be made about May 1, using Bordeaux mixture of the formula 6-3-50; a second application about June 1, using Bordeaux mixture with the formula 5-5-50 with an arsenical added, the third application as soon as the blossoms fall, the fourth about 10 days later, and the fifth and sixth at intervals of about 2 weeks, using for the third and fourth applications the Bordeaux mixture and an arsenical, and for the fifth and sixth Burgundy mixture with an arsenical.

Remedies for the San José scale. San José scale act (Ontario Dept. Agr. Bul. 157, pp. 12).—For ordinary treatment a lime-sulphur mixture is recommended. For this purpose 3 formulas of the insecticide are presented. Directions are also given for the preparation of crude oil and whale-oil soap. In summer kerosene emulsion or whale-oil soap will give satisfactory results.

A copy is given of an act for the prevention of the spread of San José scale.

The elm-leaf beetle, W. E. BRITTON (*Connecticut State Sta. Bul. 155, pp. 14, pl. 1, figs. 6*).—The biology and economic relations of this insect are briefly summarized. In combating the pest it is recommended that all locations where the beetle might hibernate in an adult stage should be searched in the spring

and the beetles destroyed. The foliage of elm trees should be sprayed with an arsenical as soon as the work of the beetle in the spring can be detected, and later in the season the pupæ may be destroyed by spraying with kerosene emulsion when they collect on the trunk of the trees or in the soil at the base.

The use of sticky bands in combating *Lasiocampa pini* (*Deut. Landw. Presse*, 34 (1907), No. 11, p. 79, figs. 10).—A brief description is given in connection with illustrations showing a method for applying sticky bands about trees in a rapid and effective manner.

Spraying calendar, S. A. BEACH ET AL. (*Iowa Sta. Bul.* 89, pp. 24, figs. 5).—Directions are presented for methods of controlling the common insects and fungus diseases which injure orchard, garden, and field crops. Recommendations are made regarding the time and method of application of the remedies, and formulas for their preparation are given.

Insecticides and fungicides, L. F. HENDERSON (*Idaho Sta. Spec. Bul.*, 1907, pp. 21).—This is a popular compilation of formulæ and recommendations for the preparation and application of the standard insecticides and fungicides.

The danger from the use of arsenic in agricultural practice, H. BERTIN-SANS and V. ROS (*Rev. Hyg. et Pol. Sanit.*, 29 (1907), No. 3, pp. 193-217).—There appears to be no means by which the attacks of leaf-eating insects may be so successfully controlled as by the use of the well-known arsenical insecticides. The necessity of using these insecticides is, therefore, recognized despite the fact that some danger attaches to their use except under proper precautions. After a thorough study of the possible dangers connected with the use of arsenicals the authors propose a set of regulations which they believe will, in large part, obviate these dangers.

It is recommended that the use of arsenate of lead for the destruction of insects be prohibited, and that other arsenical compounds should not be sold except after being colored in such a manner that they can not possibly be confused with any food, condiment, or substance used in the manufacture of wine. The buyer and seller are both to be held equally responsible for this denaturation of the arsenical, and the insecticides are to be sold in packages plainly marked "poison." It is also to be required that dealers shall make monthly reports of the amount of arsenicals sold to their customers together with their names and addresses. Treatments of vineyards with arsenical compounds are not to be authorized except during the first part of the year, and such applications are to be prohibited after the grapes are in bloom. It is also recommended that the public be warned of the danger of eating snails and slugs found in vineyards sprayed with arsenicals.

The Rex spray and other lime and sulphur compounds, L. F. HENDERSON (*Idaho Sta. Bul.* 56, pp. 12).—A comparative test was made of various forms of lime and sulphur including a proprietary mixture, one recommended by C. V. Piper, and the one commonly known as the California mixture. All of these mixtures proved exceedingly effective in the destruction of San José scale and apparently their effectiveness was about equal. The matter of the relative cost of the different forms of lime and sulphur can be determined only by repetition of the experiments, but it appears that the proprietary form in this case was not more expensive than homemade mixtures when time and labor were estimated at ordinary prices.

Observations on mosquitoes, B. GALLI-VALERIO and J. ROCHAZ-DE JONGH (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 43 (1907), No. 5, pp. 468-477, fig. 1).—As a result of their study of mosquitoes, the authors believe that a considerable percentage of the mosquitoes which first appear in spring come from hibernating larvæ and eggs. Numerous observations were made on the transportation of mosquitoes by wind and on the various parasites to which they are subject.

A test was made of a large number of substances to determine their value as repellants for mosquitoes. It was found that formalin, oil of cloves, bergamot oil, cinnamon oil, oil of peppermint, and various other essential oils had this effect to a considerable degree. In experiments in the destruction of mosquito larvae and pupae in water, it was found that green schist oil as well as petroleum and Bordeaux mixture are of considerable value for practical use. Good results were also obtained from the use of a proprietary antiseptic, depending for its action largely upon the presence of formalin.

Glossina palpalis as an agent in transmitting trypanosomiasis, L. CAZALBOU (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 12, pp. 435-437).—In experiments with dogs and cats it was found that *G. palpalis* naturally infected with trypanosomes was capable of transmitting the infection to these animals.

Some disease-carrying insects, C. E. CHAMBERS (*Clemson Agr. Col. Ext. Work*, 2 (1906) No. 5, pp. 18, figs. 5).—A brief account is given of the habits and life history of the common house mosquito, malarial mosquito, yellow fever mosquito, and house fly, with special reference to their agency in carrying diseases and to means of combating them.

Ticks in the transmission of diseases, W. DÖNITZ (*Ber. Senckenb. Naturf. Gesell.*, 1906, pp. 39-52).—In this discussion particular attention is given to *Ixodes ricinus*, *Boophilus annulatus*, *Rhipicephalus appendiculatus*, *Argas persicus*, and *Ornithodoros moubata*.

A new type of sarcoptic mite parasitic on pupiparous diptera, E. SERGENT and E. L. TROCESSART (*Compt. Rend. Soc. Biol. [Paris]*, 62 (1907), No. 10, pp. 443-445, fig. 1).—In Algeria, the domestic pigeon is infested with a parasitic fly known as *Lynchia mauri*. This fly is at times apparently parasitized by a mite described as a new genus and species under the name *Myialges anchora*. Since this family of mites is apparently confined to warm-blooded animals, it is suggested that the mite may spend the greater part of its existence on the pigeon and may merely deposit its eggs upon the parasitic fly.

FOODS—HUMAN NUTRITION.

Foods and their adulteration, H. W. WILEY (*Philadelphia: P. Blakiston's Son & Co.*, 1907, pp. XII+625, pls. 11, figs. 86).—In this volume, which is designed for manufacturers, consumers, physicians, and sanitarians, as well as for the general reader, the author has summarized a large amount of data regarding the methods of preparation and manufacture of animal and vegetable foods, their nutritive value, standards of purity, regulations for inspection, simple tests for adulterants, effects of storage, and related questions. Among the special subjects are meat and meat products, poultry and eggs and game birds, fish foods, milk and milk products and oleomargarine, cereal foods, vegetables, condiments and fruits, vegetable oils and fats and nuts, fungi as food, sugar, sirup, confectionery and honey, and invalids' and infants' foods.

In the form of appendixes, extracts are given from the national laws relating to pure food, as well as rules and regulations for the enforcement of the laws, and official standards of purity. The author calls attention to the fact that all opinions regarding adulterations, misbranding, nutritive value, and wholesomeness are individual expressions and are not to be considered in any other manner.

The volume as a whole constitutes a very interesting and valuable reference handbook and discussion of food and food adulteration.

Food inspection decisions (*U. S. Dept. Agr., Food Insp. Decisions 1-25*, pp. 28; 26, pp. 3; 27-30, pp. 4; 31, p. 1; 32, pp. 2; 33-36, pp. 4; 37-38, pp. 2; 39, p. 1; 40-43, pp. 4; 44-45, pp. 3; 46-48, pp. 4; 46 amended, pp. 2; 49-53, pp. 6;

54-59, pp. 7; 60-64, pp. 6; 65, pp. 16; 66-68, pp. 5).—The decisions which have been rendered under the provisions of the pure food law regarding the scope and meaning of the law; labeling of goods; the scope and purpose of food inspection decisions relative to importation; labeling of whisky, blends, compounds, and imitations; the use of sugar in canned foods; and related questions are taken up in these publications. They are designed to inform importers and exporters of food products and the public generally of the opinions rendered by the Secretary of Agriculture under the existing laws relating to the examination of food products before shipment to foreign countries and to the examination of food products imported into the United States and goods for interstate trade. The last of the publications mentioned contains a detailed list of the subjects taken up to date in the decisions.

Report of food commissioner, E. F. LADD (*North Dakota Sta. Rpt. 1906, pt. 2, pp. 164, pls. 4*).—Under the provisions of the State pure-food law, canned vegetables, jams, jellies, preserves, maple sirups and sugar, coffee, lard, candies and confectionery, drugs, medicines and beverages, etc., were examined. According to the author, the canned vegetables offered for sale in North Dakota are now of good quality and free from adulteration. "There has not been found on the market in this State a single brand of corn, peas, string beans, or tomatoes during the past year which contained chemical preservatives, saccharin, or coal-tar dyes." Some jams, jellies, and similar goods were found which were not true to name or which were of unsatisfactory character.

"There has been a marked improvement in the character of the maple sirups offered for sale in the State during the past year. . . .

"There has been some improvement in the character of the coffee offered for sale in the State, but there are still abuses which should be corrected. Some of these have sprung up as the result of a popular demand for a particular type of coffee, which as a rule is not to be had in any appreciable quantity, and other grades have been substituted in the place therefor."

While considerable improvement was noticeable, the quality of candies offered for sale in the State was not regarded on the whole as satisfactory, adulteration or sophistication being found in a number of cases.

Lard sold in pails or packages was not infrequently found to be short weight.

"Since the enforcement of the food law in this State there has been a marked improvement in the character of the meat products offered for sale in North Dakota. Formerly preservatives, especially sulphites and borates, were largely employed as preserving agents in meats, but after numerous prosecutions of offenders, not only local butchers but packers as well discontinued the use of preservatives as well as of coloring matter in the meat intended to be sold in this State."

The comparative merits of drawn *v.* undrawn poultry for cold storage are discussed, and, according to the author, the State food department has always intended that poultry should never be thus stored until it has been properly drawn.

Food analyses, E. H. S. BAILEY (*Bul. Kans. Bd. Health, 3 (1907), No. 2, pp. 36-39*).—The examination of a number of samples of oysters for copper showed that it was present in amounts ranging from quantities so small that it could not be readily determined to an amount equivalent to 0.09 per cent of copper sulphate.

"In regard to the occurrence of copper in oysters, this has been ascribed to various causes, but there is no evidence that would lead one to believe that it is introduced by the shipper or dealer. . . .

"Although a small amount of copper in oysters may not be an indication that

they are injurious, yet the comparatively large quantity mentioned in some of these cases indicates that such oysters should not be used as food. . . .

"Finally, it is probable that in most cases only harmless quantities of copper are found in oysters, but as far as investigations have gone it would seem that green oysters are to be regarded with suspicion, as their green color may be due to an excess of copper."

The possible harmfulness of copper salts and related questions are discussed. Brief notes are also given regarding the examination of icing materials for confectionery and other products.

Practical observations upon the chemistry of food and dietetics, J. B. S. KING ([*Chicago*]: *Blakely Printing Co., 1906, pp. 140*).—General principles of nutrition, chemistry of milk, eggs, meat, and other special foods, food for infants, food for old age, diet in various diseases, and related questions are considered.

The inspection of restaurants (*Brit. Food Jour., 9 (1907), No. 99, p. 42*).—In a brief note summarized from a statement in *Medical Press*, the desirability of inspection to insure cleanliness in restaurant kitchens is pointed out and the regulations adopted by the Westminster Council, England, are summarized.

"The rules concern the structure and capacity of the kitchen, the drainage of the scullery, and the ventilation of the premises. No food is to be stored in any place where it may be exposed to infection or contamination; proper enameled stoneware sinks are to be provided for washing vegetables in; all tables and benches are to be provided with wheels so that they may be easily moved, and shelves are to be fitted 2 in. from the walls so that dirt shall not collect in corners. The employees are to have separate places for hanging their outdoor clothes, and every part of the premises is to be adequately lighted."

Studies of the condition of Lombardy peasants, A. MENOZZI and E. GRÜNER (*Ann. Ist. Agr. [Milan], 6 (1901-1905), pp. 1-25, pls. 2*).—The present investigation was made on farms in the province of Milan. The data recorded include a discussion of food supply, sanitation, kinds and amounts of food eaten, and related questions.

Nutrition on an unrestricted diet, S. SUNDSTRÖM (*Skand. Arch. Physiol., 19 (1907), No. 1-3, pp. 78-95*).—The dietary studies reported were made with Finnish students and laborers. The diet of the students supplied on an average 157 gm. protein and 3,984 calories per person per day, that of one group of laborers 114 gm. protein and 3,011 calories, and of the other group, 167 gm. protein and 4,378 calories. In the case of the students, animal food furnished about 75 per cent of the total protein, and in the case of the laborers, some 60 to 66 per cent.

A new chemical test for strength in wheat flour, T. B. WOOD (*Proc. Cambridge Phil. Soc., 14 (1907), No. 1, pp. 115-118*).—In his work on this subject, the author has studied the conditions which influence the volume of the loaf produced from a given weight of flour and especially carbon dioxid production and its relation to the sugar originally present in the flour.

The carbon dioxid evolved was measured and the amount of sugar necessary to produce it was calculated and compared with the quantity found in the flour. The latter quantity was not nearly sufficient to account for all the carbon dioxid evolved by the yeast, but the author believes that the discrepancy may be accounted for by the action of the diastatic enzymes present in the flour and that the determination of the sugar content of flour and its relation to carbon dioxid production is of value in judging baking quality.

Generally speaking, the experiments showed that the amount of carbon dioxid produced had a direct relation to the quality of flour as judged by bakers.

"In applying the above ideas to testing flours, there are clearly two ways of

proceeding: (1) To make chemical determinations of the sugar contained in the flour as such and of the sugar formed by incubating the mixture of the flour and water at such a temperature and for such time as is commonly used in baking (for instance, for 3 hours at 30° C.); (2) to mix the flour with yeast and water and measure the carbon dioxide evolved during the fermentation.

"Of these two methods the latter is very much easier to carry out and, it is suggested, gives very valuable indications of that particular component of strength which is concerned with the volume of the loaf. If this is so, the addition of sugar to flours which make small loaves should produce an increase in size, and this has been found to be the case by actual baking experiments. For instance, in one experiment the addition of 1 per cent of sugar to ordinary household flour as bought in Cambridge was found to make an increase of 2 per cent in the weight and 13 per cent in the volume of the loaf."

Experiments on the nutritive value of different sorts of bread, P. FAUVEL (*Rev. Internat. Palsif.*, 20 (1907), No. 1, pp. 19, 20).—The author summarizes and discusses the results of his investigations, which showed that breads including the whole of the wheat berry furnished less nutritive material pound for pound than white bread because of their inferior digestibility. The effect of different sorts of bread on the excretion of uric acid, xantho bodies, urea, and phosphoric acid, and upon the volume and acidity of the urine is spoken of.

The microscopic examination of bread, E. COLLIN (*Ann. Chim. Analyt.*, 12 (1907), No. 2, pp. 41-49, figs. 4).—The results of microscopical examinations of bread of different sorts are reported and illustrated by figures. The author believes that such examination is valuable for the detection of adulteration of bread as with other flour than wheat and may also be used for alimentary pastes.

A contribution to the bacteriological study of bread and biscuits, C. M. BELLI (*Gior. R. Soc. Ital. Ig.*, 28 (1906), No. 6; *abs. in Hyg. Zeitbl.*, 2 (1907), No. 12, pp. 359, 360).—According to the investigations reported, both bread and biscuits or crackers are sterile when taken from the oven. For some time after baking, 22 hours in the case of bread and a month in the case of crackers, the micro-organisms present were few in number. This is an indication, in the author's opinion, that such foods, owing to dryness or dry crust and to any acidity, are not very favorable ground for the growth of micro-organisms, as there is abundant opportunity to acquire them from the air.

Enlargements of micro-photographs of barley grains rich in protein and poor in protein, LAUCK (*Wechschr. Brau.*, 24 (1907), No. 13, pp. 175, 176, figs. 7).—The micro-photographs reproduced are of interest as showing the variations in the structure of the grain and the distribution of protein and starch in barley of varying composition.

Comparative tests of German and American oats, E. HASELHOFF (*Landw. Vers. Stat.*, 65 (1907), No. 5-6, pp. 339-347).—The analytical data reported showed practically no difference in the composition of American and German oats, and in the author's opinion the German oats are as well suited for the manufacture of oat foods as the American.

The extractives of muscles. VIII, The formation of histidin by the cleavage of carnosin, W. GULEWITSCH (*Ztschr. Physiol. Chem.*, 50 (1907), No. 6, pp. 535-537).—According to the author, carnosin is the first leucomatin which has been recognized as a histidin derivative.

Studies of the lecithin content of myocardium and striated muscles, A. ERLANDSEN (*Ztschr. Physiol. Chem.*, 51 (1907), No. 1-2, pp. 71-155).—The monoamido-monophosphatids—that is, the lecithins of the cephalin group—are best known and perhaps most widely distributed in the body. The composition of the lecithins of beef muscle and heart was $C_{56}H_{102}NPO_8$, these proportions being similar to those for the lecithin of hen's egg yolk. Methods of estimat-

ing lecithin and other questions which have to do with the different radicals present in this substance are discussed at length.

On the changes in certain meat essences kept for several years in tins, G. S. BUCHANAN and S. B. SCHRYVER (*Local Govt. Bd. [Gt. Brit.], Med. Dept., Rpts. Insp. Foods, 1906, No. 1, pp. 11*).—Samples of essence of beef in tins, which were several years old and had been returned from South Africa, were not in good condition, as was shown by the appearance of the cans and can contents. Chemical and physiological studies were therefore made of such goods.

"The only substantial difference that could be detected in the old samples as contrasted with the new was that the former contained appreciable quantities of metal which has been dissolved out from the tin and reprecipitated in insoluble form, whereas the latter was free from such metals. The metal consisted almost entirely of tin with only the smallest traces of lead. . . .

"With regard to the organic contents of the several tins, the general conclusion may be drawn that these have undergone very little change. If products of the nature of meat extracts and essences be put on the market in glass vessels, there is no reason why they should not remain in good condition for indefinite periods, especially when it is remembered that they can be sterilized in small bulk. These remarks are intended to apply only to such bodies as extracts or essences which contain no coagulable protein. They would hardly apply, for example, to such products as meat juices."

When samples of the meat essences properly diluted with physiological saline solution were injected into the peritoneal cavities of rabbits no disturbances were noted. "The old samples were perfectly nontoxic under these conditions."

Oysters, S. J. CRUMBINE (*Bul. Kans. Bd. Health, 3 (1907), No. 2, pp. 40, 41*).—The author insists that oysters should not be floated or fattened and that sanitary measures should be followed when they are shipped in bulk.

"Most people regard the white, plump oyster as preferable to the gray, rather thin oyster. The natural color of the oyster is a dingy gray, sometimes slightly tinged with green or red, according to the locality where grown and the time of year they are gathered. The white plump oyster is the one that is water-soaked and bleached and has lost the 'sea flavor.' The size of the oyster depends in the main on age, the very large ones being from four to five years old."

Note on the value of cocoa as a food and condiment, R. O. NEUMANN (*Arch. Hyg., 60 (1907), No. 3, pp. 175-190*).—The author gives a revision of some of the calculations in his previously published article on this subject (*E. S. R., 18, p. 757*), but states that the revised figures do not in any way change the conclusions which were reported.

Fresh-water algæ as human food, S. NAMIKAWA (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1906), pp. 123, 124; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 530, II, p. 884*).—Two edible Japanese marine algæ are described and an analysis of one species is reported.

The digestibility and utilization of some polysaccharid carbohydrates derived from lichens and marine algæ, T. SAIKI (*Jour. Biol. Chem., 2 (1906), No. 3, pp. 251-265*).—By means of artificial digestion experiments and experiments with small dogs and a man, studies were made of the digestibility of the carbohydrates of lichen and algæ, including among others Iceland moss (*Cetraria islandica*), Irish moss (*Chondrus crispus*), and agar-agar. The experiments indicated, in the author's opinion, that the polysaccharid carbohydrates "were not readily transformed to sugar by carbohydrate-digesting enzymes of animal origin and scarcely more readily by vegetable enzymes or bacteria. Correspond-

ing with this, the digestibility and availability of such products in the alimentary tract were found to be very imperfect in both man and animals. The results of these investigations should be applied in criticism of the claims made for some of the 'food preparations' rich in indigestible carbohydrates, and many food materials more properly rated as 'food accessories.'"

The effect of the agar-agar on the total mass of the feces in an experiment with man was very marked. "The agar easily retains water in the alimentary residues and prevents the formation of dry, hard, fecal masses which readily induce constipation. This property of the agar, together with its failure to dissolve readily by digestion or fermentative change has led . . . to . . . its use in appropriate cases of chronic constipation with very satisfactory results."

In one of the experiments with man unboiled Italian chestnuts were added to the regular diet to ascertain the effect of raw starch on the composition of the feces as compared with the alge carbohydrates. "The results indicate the relative indigestibility of starch offered in this form."

Raspberry juice and marmalade, O. LÖBECK (*Ztschr. Öffentl. Chem.*, 13 (1907), No. 5, pp. 84-90).—From an examination of a number of samples of raspberry juice and raspberry marmalade, the author concluded that the German goods were superior to the French or the English. Some of the samples examined contained excessive amounts of seed.

The composition of English fermentation vinegars, F. D. RATCLIFF (*Analyst*, 32 (1907), No. 372, pp. 85-87).—Detailed analyses of 11 samples of vinegar are reported. A discussion follows the paper.

The sensation of hunger; its location and cause, L. LUCIANI (*Arch. Physiol.*, 3 (1906), No. 5, pp. 541-546).—A physiological discussion.

Experimental studies on the effect of condiments on the secretion of gastric juice, RHEINBOLDT (*Ztschr. Diätet. u. Phys. Ther.*, 10 (1906), p. 35; *abs. in Hyg. Rundschau*, 17 (1907), No. 3, pp. 190, 191).—Experiments with hospital patients with fistula and a dog with so-called Pawlow small stomach led to the conclusion that the soup flavoring studied caused an increased flow of gastric juice with higher acid content. In the case of man this juice had normal digestive powers, but in the case of the dog it was inferior to normal gastric juice in this respect.

The assimilation of iron by nursing children, KRASNOCORSKY (*Jahrb. Kinderheilk.*, 64 (1906), p. 651; *abs. in Zentbl. Physiol.*, 20 (1906), No. 23, p. 785).—As shown by a number of experiments, iron of woman's milk was much better absorbed than that of goat's milk and iron in cooked milk better assimilated than in raw. Sixty per cent of the iron in spinach and egg yolk was assimilated. A considerable part of the iron of commercial preparations was also found to be assimilated, though such goods were inferior to the mothers' milk, spinach, and egg yolk in this respect.

Percentage composition and relative money value, digestibility and use of food, J. KÖNIG (*Prozentuale Zusammensetzung und Nährgehalt der menschlichen Nahrungsmittel nebst Ausnutzungsgrösse derselben und Kostsätzeu.*, Berlin: Julius Springer, 1906, 9. ed., pp. 8, charts 4; *rev. in Hyg. Zentbl.*, 2 (1907), No. 9, pp. 256, 257).—A revised edition of this series of food charts with explanatory text.

Concerning digestibility and especially the digestibility of protein, W. GRIMMER (*Biochem. Ztschr.*, 2 (1906), No. 2, pp. 118-143).—The author's investigations with horses are reported and discussed in comparison with similar work of other investigators.

The acidity of the mixed stomach contents he found to be low at the beginning of digestion owing to the large amount of alkaline saliva present. It increases gradually and after about 45 minutes becomes nearly constant, being

equivalent to about 0.3 per cent hydrochloric acid. As a matter of fact, however, the hydrochloric acid actually present is much less than this quantity, as the acidity is largely due to lactic acid or later to peptones. The material in the small intestine during the entire period of digestion has an alkaline reaction equivalent on an average to about 0.13 or 0.14 per cent sodium carbonate.

The digestion and resorption of nutrients in the stomach and intestine increased as the digestion progressed. As regards the protein cleavage products in the stomach when oats were fed, syntonin was present in large quantities at the beginning of the digestive period, constituting in amount over one-third of the total soluble nitrogen. The proportion of syntonin later on decreased. The quantity of albumoses of different sorts increased from the beginning of the digestive period until a maximum was reached and then diminished. At the beginning of the period the amount of peptone present was very small and it was not formed in large proportion in the stomach until after 3 hours. It may be said that peptone is practically the only cleavage product which is absorbed in the stomach, and peptones and crystalline cleavage products in the small intestine.

Concerning creatin and creatinin in metabolism in man, K. O. AF KLERCKER (*Biochem. Ztschr.*, 3 (1907), No. 1, pp. 45-87, figs. 6).—From the experimental data reported the author concludes that it is very questionable whether there is any biological relation between creatin and creatinin.

When they are taken into the body both may be in part excreted unaltered through the kidneys and no change from one to the other takes place in the body. Creatinin is the more readily and completely excreted in the urine. Since exogenous creatin is not changed to creatinin in the body and since, further, the ordinary diet supplies only traces of creatinin, the quantity in the urine must be of endogenous origin, but the way in which it is formed in the body is not known. A relationship between it and the creatin of the muscular system is not proved and does not seem probable. Since creatin can not be regarded as a cleavage product of protein taken in the diet, there seems hardly any alternative except to regard it as a special metabolic product.

The physiological action of muscle extract, J. G. SLADE (*Jour. Physiol.*, 35 (1907), No. 3, pp. 163-181, figs. 10).—To determine the effect of such materials as meat extract, a number of experiments are reported, in the majority of which a special extract, prepared in such a way that it contained practically no salts nor proteids, was used. Tests were also made with some of the known constituents of muscle extract, such as xanthin, creatin, and urates. The conclusions which were drawn follow:

“Muscle extract has no stimulant action upon the central nervous system, nor upon the power of doing physical work, in man. If it be taken as a strong solution and in large amounts it is liable to cause purgation. In moderate doses it increases the rate and activity of the heart. This is not due to creatin, xanthin, or urates. The vessels are constricted. After small doses there is initial dilatation. The movements of plain muscle throughout the body are increased. Probably this is due to ornithin and novain.

“Muscle extract in 0.5 per cent solution increases the work of voluntary muscle; in 0.1 per cent solution it has no effect upon the efficiency of the muscle; in 2 per cent solutions it decreases the work. Xanthin has an action corresponding to the first effect—that is, in saturated solution (1-2500) it increases the work. Creatin has no action on voluntary muscle.

“The effect of fatiguing a muscle before preparing an extract from it is to increase its extractives and increase the activity of the extract. If injected into animals it causes great languor, prostration, and all the symptoms characteristic of fatigue. Muscle extract administered as ‘beef-tea’ acts as

a moderate diuretic to men and other animals. The diuresis is associated with vaso-dilatation of the kidney."

The excess of energy due to the elimination of protein and its measurement. A. CHAUCHEAU (*Compt. Rend. Acad. Sci. [Paris]*, 144 (1907), No. 5, pp. 237-243).—The measurements of energy reported during the digestion and utilization of different nutrients showed, according to the author, that more energy is given off as heat when protein is assimilated than is the case with other nutrients. In general, the energy expenditure of a fasting subject is augmented when the subject is fed, by the energy necessary for the digestion, absorption, and assimilation of nutrients.

The different nutrients do not require the same expenditure. Variations of this character are shown and explained very well in the case of assimilation, which is accomplished by the incorporation of food potential into reserve fat. With carbohydrates and fat the incorporation is accomplished economically, the fat having only to be adapted to its new situation, while the carbohydrates have to be converted into fat by a simple process that is practically neutral from a thermic point of view. With respect to protein the transformation into fat is much more difficult. The production of the fat reserves at the expense of the food proteid explains, therefore, very well the greater energy expenditure connected with the usage of the meat ration. This production results in an incomplete oxidation (to urea) of the potential proteid, an oxidation which liberates a notable quantity of energy without other utilization than that of the chemical metabolism for which the energy is employed.

With very large meat rations the actual energy thus employed for the formation of reserves of fat has a considerable value, but the ration need not be excessive for the process of transformation of protein and fat to occur. Even in small quantity the protein of the ration fulfills its double destiny of working for the renovation of the tissues and of concurring in the maintenance of a fat reserve. The result of this is that the greater expenditure of energy connected with a meat diet manifests itself clearly in the case of subjects nourished with rations capable only of maintaining an equilibrium of nutrition.

All of these facts are incompatible with the principle of isodynamic substitution. The nutritive value of the nutrients is not to be sought in their heats of combustion. The theory of food and nutrition can no longer be presented in such simple fashion.

Concerning protein metabolism, J. HÄMÄLÄINEN and W. HELME (*Skand. Arch. Physiol.*, 19 (1907), No. 1-3, pp. 182-200).—When egg white, "protone," and roast veal were each added to a basal ration it was found that the excretion of the extra nitrogen was slower on the egg diet than on the other diets. Similar results were also noted with the sulphur excretion, the extra sulphur of "protone" and veal being recovered in 2 or 3 days as compared with 6 days in the case of the egg white. The experimental data are not regarded as sufficient for general deductions regarding the excretion of phosphorus.

The chemical mechanism of protein assimilation, C. INAGAKI (*Ztschr. Physiol. Chem.*, 50 (1907), No. 6, pp. 449-471).—Experiments made with cells and isolated cell nuclei led to a number of general conclusions. According to the author, nucleohiston unites with albumoses and forms salt-like bodies when it is in a free or dissociated condition, and it follows that albumoses formed in the body or artificially introduced into the circulation can be taken up or fixed by the cell substance.

Nitrogen balance on a mixed ration low in protein, G. SPADARO (*Arch. Fisiol.*, 3 (1906), No. 5, pp. 533-538; *abs. in Zentbl. Physiol.*, 20 (1906), No. 23, p. 789).—The author found that in a 4-day experimental period he was practically in nitrogen equilibrium on a mixed diet supplying 15.3 gm. nitrogen per

day. The nitrogenous constituents of the ration were then increased to what he considered the limit of tolerance, 500 gm. meat and 140 gm. cheese, and after a preliminary period of 9 days an experiment covering 4 days was made. Although the diet furnished 32.7 gm. nitrogen per day, nitrogen equilibrium was not reached, there being an average daily loss of 1.1 gm. nitrogen.

Gelatin as a substitute for protein, P. RONA and W. MÜLLER (*Ztschr. Physiol. Chem.*, 50 (1907), No. 4-5, pp. 263-273).—In the experiments reported, which were made with dogs, gelatin was supplemented by tyrosin and tryptophan, and confirmed the opinion that gelatin nitrogen may replace 20 per cent of the proteid nitrogen of the diet. The adding of the amido acids (tyrosin and tryptophan) did not increase the substituting value of the gelatin.

Has the amount of soluble nitrogenous compounds in wheat flour an effect upon baking value? W. BREMER (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 13 (1907), No. 2, pp. 69-74).—The experimental data reported indicate that it is doubtful whether the soluble nitrogenous constituents affect baking quality.

The influence of lecithin upon the action of digestive ferments, S. KÜTTNER (*Ztschr. Physiol. Chem.*, 50 (1907), No. 6, pp. 472-496, *dgm.* 1).—In some cases lecithin increased and in others diminished the action of both peptone and pancreatic ferments. No explanation of this was found, but the author states that his experiments are to be continued.

The excretion of sodium chlorid and nitrogenous material through the skin, SCHWENKENBECHER and SPITTA (*Arch. Expt. Path. u. Pharmacol.*, 56 (1906), pp. 284-300; *abs. in Chem. Zentbl.*, 1907, I, No. 11, p. 832).—According to the authors nearly the same quantities of sodium chlorid and nitrogen are excreted through the skin, the value for each being about 0.33 gm. for 24 hours in the case of a healthy man lying in bed. If excessive secretion is induced by heat, by pilocarpin, or by certain diseases, the excretion of sodium chlorid is diminished to 0.05 per cent.

The transformation of formic acid and formates and their elimination, C. FLEIG (*Compt. Rend. Acad. Sci. [Paris]*, 114 (1907), No. 7, pp. 386-388).—The formation of carbonates from formates in the animal body under different conditions was the subject of the author's investigations.

Cooking utensils injurious to health, O. SCHÜTTE (*Pure Products*, 3 (1907), No. 4, pp. 163-169).—Possible dangers from the use of metal and other cooking utensils are spoken of with special reference to conditions which exist in different countries.

ANIMAL PRODUCTION.

Practical details of vital significance in the utilization of corn fodder. Silage from dried corn fodder, A. T. NEALE (*Delaware Sta. Rpt.* 1903, pp. 36-40).—Brief statements are made regarding the steam husker and fodder shredder and as to the air-blast elevator and its use in making circular stacks and ricks. Tests were undertaken to determine approximately the completeness of separation by the air blast of the blade and top fodder from the coarser portions of the stalk, but were not carried out to the author's entire satisfaction, though in one instance a separation into light and heavy portions, i. e., into blades and coarser material, was accomplished.

Formerly good results were obtained locally by feeding cut fodder packed into boxes, moistened with hot water, and allowed to stand for 24 hours. "The concentrated feeds, say cotton-seed meal, can be mixed with this mass and one of the reasons for purchasing bran can thereby be avoided."

This method is too inconvenient for general use, but it suggested the possibility of making silage from dried fodder, and several successful experiments are reported on the conversion of dried corn fodder into silage by the addition of

water and subsequent fermentation. A rise in temperature was noted in the silos and the development of an aromatic odor as in the case of green silage. It was noted that both young and old stock ate such silage practically without waste, and that cows preferred it to dried shredded fodder. "It is a better and a safer mass to use with cotton-seed meal than dried fodder or hay. The meal adheres to the damp fodder, can not be separated from it by the stock, mastication is insured, and impaction of cotton-seed meal prevented. . . ."

"In this experiment the quality of the fermented product varied. Where the moisture content was normal the aromatic odor above noted was present. No points of excessive moisture were found. Fodder in the bottom of the silo was not as moist as that nearer the top. In places channels had formed through which the water, pumped upon the surface, had flowed, leaving masses of only partially moistened fodder in which, to a limited extent, a musty smell and visible mold in extreme cases were noted. This was also the case in the product stored in immediate contact with the cemented lining of the silo, a condition also likely to exist in silage made from green cornstalks.

"The fact that fire risks were noticeably decreased by moistening the fodder corn was patent to all observers."

Calculated loss from the heating of moistened corn fodder, C. L. PENNY (*Delaware Sta. Rpt. 1903, pp. 40, 41*).—In connection with the studies noted above on silage making from dried corn fodder moistened with water, the loss of material from the fermentation of the silage was calculated.

According to the author, "100 lbs. of the fodder would lose 2.81 lbs. of starch, or its equivalent, to produce through its complete fermentation the necessary heat to raise the temperature of the mass to 165° F., and this amount, 2.81 lbs., is just 6 per cent of the total dry matter of the fodder."

Bacteriological studies of ensiled forage, C. GORINI (*Ann. Ist. Agr. [Milan], 6 (1901-1905), pp. 105-122, pls. 2*).—The results are reported of a study of the bacteria present in forage preserved in silos.

Feeding saccharified starch, J. HANSEN (*Illus. Landw. Ztg., 27 (1907), No. 15, p. 130*).—Starch in the form of starch paste, when converted into sugar by the action of a diastatic ferment, was found to be a valuable material for supplementing skim milk in calf feeding. The relative economy of treating starch with the diastase and related questions are spoken of, the article as a whole being a summary of a paper presented before the German Dairy Society.

A method for the preparation of a preservable dry fodder from yeast (*Pure Products, 3 (1907), No. 3, p. 123*).—Compressed waste yeast from breweries, it is stated, may be converted into a feeding stuff of good keeping qualities by heating such material to which common salt has been added, to about 70° for some 5 minutes. This converts it into a gelatinous mass, which combines readily with other materials and may be mixed with such feeds as spent hops, malt sprouts, grain, beet chips, etc. The treated yeast possesses little enzymatic power. If chopped straw constitutes a part of the mixture the mechanical condition is improved and the material dries more readily.

The feeding stuff control law, A. GOSS and W. J. JONES, JR. (*Indiana Sta. Circ. 6, pp. 10*).—The text of the Indiana feeding-stuff law is given, together with suggestions as to the way manufacturers and dealers may best comply with its requirements. The law, which is similar in its scope and administration to the State fertilizer law, provides for the filing of samples with the State chemist and their analysis, the fixing of labels or tags, the filing of sworn statements by manufacturers, importers, dealers, and agents of the quantity and kind of commercial feeding stuffs sold, and for the punishment of violations of the law by fines.

Animal industry in Belgium in 1905 (*Bul. Agr. [Brussels], 23 (1907), No. 2, pp. 162-171*).—A summary of statistics regarding the horses, cattle, pigs, and sheep in different Belgian provinces.

Calves for the dairy interests, A. T. NEALE (*Delaware Sta. Rpt. 1903, pp. 35, 36*).—The possible profits to be obtained in raising young cows for sale in dairy districts and in raising young stock of beef types for fattening on surplus corn are discussed.

The production of winter lambs, G. C. HUMPHREY and F. KLEINHEINZ (*Wisconsin Sta. Rpt. 1906, pp. 47-55, figs. 4*).—Four grade ewes, 1 pure-bred Hampshire and 1 pure-bred Southdown ewe in pasture during the summer were bred to a Southdown ram. Early in the winter the ewes were taken to the sheep barn. The lambs were dropped about the 15th of December. At lambing time and for some 3 weeks afterward the ewes and lambs were kept in warm pens. During the trials the ewes were fed a mixture of oats, bran, and oil meal 20:10:1 with alfalfa hay and corn silage, the total cost of their winter feed to the close of the test being estimated at \$3.98 each. After the lambs were taken from the lambing pen to the sheep barn they had access to alfalfa hay and were fed bran, oats, corn meal, and oil meal 4:2:2:1. The average weight of the lambs at birth was 8.7 lbs., and they were sold at an average age of 59.5 days, at an average weight of 41.7 lbs. The calculated net profit per lamb was \$7.26. On an average the dressed weight was 52 per cent of the live weight. Other data regarding the slaughter test are recorded.

"In conclusion it may be said that the most disappointing feature of this trial was the failure to get more ewes to breed early enough to produce winter lambs. Where one can secure grade or pure-bred Dorset ewes and have them in good condition, there seems to be little question about their breeding in July, while with the other breeds, one can not depend upon them, and it is only in exceptional cases that they will breed at that season of the year. The use of the Southdown ram gave compactness and excellent mutton quality to the lambs, and the cross is one which can be recommended. The price received for the lambs was extraordinary, but it emphasizes the fact that it pays to produce something of special value and cater to a high-class trade which demands only the best."

Earlier work has been previously reported (*E. S. R., 18, p. 263*).

Dried beet pulp for lambs, G. C. HUMPHREY and F. KLEINHEINZ (*Wisconsin Sta. Rpt. 1906, pp. 56-59*).—When 10 lambs were fed whole oats and dried beet pulp 1:1 with clover hay ad libitum, the average gain per head in 13 weeks was 22 lbs., as compared with an average gain of 22.2 lbs. in the case of a similar lot fed under the same conditions a grain ration of whole oats and shelled corn 1:1. The grain eaten per pound of gain on the dried beet pulp was 4.14 lbs. and the coarse fodder 8.01 lbs. Similar values for the corn ration were 4.10 and 7.94 lbs., respectively. Ten days before the close of the trial the lambs were sheared, the dried beet pulp lot yielding 85.5 lbs. of wool and the corn fed lot 80.9 lbs. The feeding stuffs used were analyzed.

"It may be said that both feeds were satisfactory and practically equal for producing growth when used in connection with whole oats and clover hay. The health and the condition of the 2 lots were all that could be desired. . . . Dried beet pulp costs in the neighborhood of \$15 per ton. Its economical use will depend on the price of corn. Last winter the shelled corn cost about \$18 per ton, which made the ration of beet pulp and oats considerably more profitable."

Whole corn compared with corn meal for fattening pigs, with summary of trials for ten years, W. A. HENRY and D. H. OTIS (*Wisconsin Sta. Rpt.*

1906, pp. 18-32).—Continuing earlier work (E. S. R., 18, p. 266), 3 tests are reported.

In the first, corn (both whole and ground) and wheat middlings 1:1 with 2 lbs. of skim milk per head daily were fed. The total gain in 12 weeks made by the 12 pigs fed the whole-corn ration was 1,295 lbs. and by the similar lot fed the ground-corn ration, 1,298 lbs. The 2 lots required 3.60 and 3.66 lbs. of grain and 1.66 and 1.54 lbs. of skim milk per pound of gain, respectively. In the second test corn (whole and ground) and wheat middlings 2:1 without skim milk were fed for 12 weeks to 2 lots of 5 pigs each. On the whole-corn ration the total gain was 549 lbs. and the grain eaten per pound of gain 4.71 lbs. Similar values for the lot fed the corn-meal ration were 701 lbs. and 4.42 lbs. In the third trial the shelled corn and corn meal, supplemented in each case by wheat middlings, were compared with 2 lots of 6 pigs each, pastured on rape. On the whole-corn ration the total gain was 711 lbs. and on the corn-meal ration 909 lbs., the grain eaten per pound of gain being 4.90 and 3.99 lbs., respectively.

Considering the 10 years tests as a whole, the average gain on whole corn has been 768 lbs. per lot of 8 pigs, and on corn meal 883 lbs., the feed eaten per pound of gain in the 2 cases being 5.01 and 4.71 lbs., or an economy of 6 per cent in favor of the ground grain.

"Where there is plenty of time for maturing the pigs, and it is not necessary to secure the maximum daily gain, it is doubtful if it pays to grind corn for pigs. The test shows that where quick maturity is an important item better results are secured from the corn meal. Pigs fed corn meal eat more grain and make somewhat larger daily gains. Corn meal can doubtless be used to good advantage in finishing off a bunch of hogs which were first fed shelled corn. Changing over to corn meal near the close of the feeding period also furnishes a change in the character of the ration which will be satisfactory to the animals.

"There are conditions and circumstances where it is not advisable to grind the corn even though the corn be high priced. On the other hand, when fitting hogs for show, sale, or in high-pressure feeding for market, the feeder will consider it advisable to grind the corn, even though it is expensive to do so. The feeder, knowing these results, will use them to suit his own conditions."

Soy-bean meal versus wheat middlings as a supplement to corn meal for growing and fattening pigs, G. C. HUMPHREY and J. G. FULLER (*Wisconsin Sta. Rpt. 1906, pp. 33-41, fig. 1*).—When corn meal and soy-bean meal 2:1 were compared with a like proportion of corn meal and wheat bran with 2 lots of 5 pigs on rape pasture, the average daily gain in 12 weeks on the soy-bean-meal ration was 0.75 lb. per head and on the wheat-middlings ration 0.73 lb. Skim milk was fed with the grain and in the last half of the period was mixed with it in equal amounts to form a thick slop. The 2 lots consumed per pound of gain 3.06 and 3.05 lbs. grain and 3.34 and 3.35 lbs. skim milk, respectively, quantities which are practically the same. The pigs were then taken off the pasture and given the same grain and skim-milk rations in pens for 12 weeks. The average daily gain on the soy-bean-meal ration was 1.32 lbs., and 3.57 lbs. each of grain and skim milk was consumed per pound of gain. With the lot fed wheat middlings the average daily gain was 1.23 lbs. per head, 3.85 lbs. of both skim milk and grain being consumed per pound of gain. As shown by a slaughter test, there was practically no difference in the percentage of dressed weight for the 2 lots. The kidney fat in the lot fed the soy-bean ration constituted 3.3 per cent of the total carcass and in the wheat-middlings lot 2.9 per cent. The feeding stuffs used were analyzed.

"Soy-bean meal mixed with corn meal in the proportion of 1:2 produces greater gains than wheat middlings and corn meal fed in the same proportion.

In feeding equal amounts of the 2 rations, soy beans and corn meal supply a slightly higher per cent of dry matter and digestible matter than wheat middlings and corn meal.

"For firmness, fine grain and texture of flesh, and even distribution of fat and lean, the ration of wheat middlings and corn meal is superior to that of soy beans and corn meal."

Earlier work has been reported (E. S. R., 18, p. 266).

Liquid food for young pigs and other young animals, E. THIERRY (*Jour. Agr. Prat., n. ser., 13 (1907), No. 15, p. 464*).—A discussion of the value of hay tea, porridge from rice or other cereals, and meat broth for feeding young animals.

Work of the department of horse breeding, A. S. ALEXANDER (*Wisconsin Sta. Rpt. 1906, pp. 288-291*).—A brief note on the station work on horse breeding, most of which is summarized from a previous publication (E. S. R., 18, p. 764).

DAIRY FARMING—DAIRYING—AGROTECHNY.

The university dairy herd, 1905-6, G. C. HUMPHREY and F. W. WOLL (*Wisconsin Sta. Rpt. 1906, pp. 60-90, figs. 2*).—The records of the station herd during the year are reported and discussed in the same form as in the previous report (E. S. R., 18, p. 273).

The herd comprised 32 cows representing Jersey, Guernsey, Holstein, Shorthorn, Red Polled, and Brown Swiss breeds. Three cows added to the herd during the year are described. The tabulated data show the amounts of the different kinds of feeds consumed and the milk and butter produced by 30 cows for which a full year's record was obtained. The average yield for the herd was 7,328.6 lbs. of milk and 303.54 lbs. of butter fat. The largest yield of butter fat, 449.73 lbs., was produced by a grade Red Polled cow. The average net profit per head was \$41.20 as compared with \$35.20 during the preceding year.

The average production of the 30 cows by breeds was as follows: Jersey (7 cows), 6,247.7 lbs. of milk and 318.46 lbs. of butter fat; Guernsey (7 cows), 6,461.1 lbs. of milk and 306.56 lbs. of butter fat; Holstein (7 cows), 10,176.4 lbs. of milk and 346.34 lbs. of butter fat; Shorthorn (3 cows), 4,967.7 lbs. of milk and 185.36 lbs. of butter fat; Red Polled (4 cows), 7,712.3 lbs. of milk and 300.07 lbs. of butter fat; and Brown Swiss (2 cows), 6,954.3 lbs. of milk and 275.19 lbs. of butter fat. The average butter fat production of these breeds for 1898 to 1906 was as follows: Jersey, 312.6 lbs.; Guernsey, 297 lbs.; Holstein, 337.5 lbs.; Shorthorn, 264.7 lbs.; Red Polled, 295.5 lbs.; and Brown Swiss, 278 lbs.

As in previous reports, a comparison was made of the different cows by types. The data are considered unfavorable to the dual-purpose type.

Analyses were given of the feeding stuffs used. In general it was found that a large production was associated with the feeding of a ration containing a high amount of dry matter or digestible protein and a narrow nutritive ratio.

The value of individual records of dairy cows, B. E. CARMICHAEL (*Ohio Sta. Circ. 67, pp. 10, figs. 3*).—The records of 2 cows for 3 years are presented in this circular for the purpose of illustrating the value of accurate knowledge concerning the production of each cow in the dairy herd. One cow produced on an average for 3 years 5,754.9 lbs. of milk and 330.2 lbs. of fat at a profit of \$50.72 over cost of food, and the other cow 7,365.1 lbs. of milk and 231.4 lbs. of fat at a profit of \$24.82. These are not believed to be extreme differences, but such as might be found in average untested dairy herds.

Roots supplementary to silage for dairy cows, R. S. SHAW and H. W. NORTON, Jr. (*Michigan Sta. Bul. 240, pp. 19-31*).—Three feeding experiments

were conducted for the purpose of determining if the addition of roots to a complete ration containing silage would increase profitably the yield of milk. The first experiment was made in the spring of 1905 with 2 lots of 8 cows each and lasted 6 weeks. The second experiment was made in the spring of 1906 with 2 lots of 7 cows each and lasted 8 weeks. The third experiment was also made in the spring of 1906 with 2 lots of 5 cows each and lasted 8 weeks.

The results of the three experiments showed that the addition of roots to a complete ration, consisting of silage, clover hay, and grain increased the yield of both milk and butter fat but not sufficiently to compensate for the increased cost of production. When roots are fed, the increase in cost of milk was 4.2 cts. per 100 lbs. and the increase in cost of butter fat was 1.16 cts. per pound. The fat content of the milk was not affected. The increase in the live weight of the animals was greater when roots were fed, but the difference was not very marked.

A new milking machine (*Umschau*, 11 (1907), No. 12, pp. 233, 234, figs. 2).—A new hand milking machine is illustrated and described.

The feeding of sheep for the production of Roquefort cheese, E. MARRE (*Prog. Agr. et Vit.*, 24 (1907), No. 15, pp. 451-454; *Prog. Agr. et Vit. (Ed. l'Est)*, 28 (1907), Nos. 16, pp. 475-480; 17, pp. 506-512; 18, pp. 528-535).—This discussion is based upon information obtained from numerous sheep raisers in the region of Roquefort.

The inspection of milk production, A. MONVOISIN (*Rev. Gén. Lait*, 6 (1906), No. 6, pp. 131-137).—The author discusses the needs and methods of milk inspection.

The inspection of milk, P. ADAM (*Rev. Sci. [Paris]*, 5, ser., 7 (1907), No. 16, pp. 495-499).—This is a discussion of the judging of the purity of milk by means of analytical and other data.

Ammonia in milk and its development during proteolysis under the influence of strong antiseptics, H. C. SHERMAN ET AL. (*Jour. Biol. Chem.*, 3 (1907), No. 2, pp. 171-175).—The results of the investigations are summarized by the authors as follows:

"Analyses of a large number of samples of mixed milk as sold in New York City showed an average of 0.0004 per cent of ammonia preformed at the time of examination together with an additional 0.0003 per cent of what is here called 'cleavage' ammonia.

"When ordinary milk is allowed to become stale the amounts of both preformed and 'cleavage' ammonia usually increase.

"Addition of 3 per cent of chloroform or 0.1 per cent of formaldehyde retards but does not stop proteolysis which results in the formation of ammonia. The production of those proteolytic products to which the 'cleavage' ammonia is due appears to be retarded by these antiseptics to a greater extent than is the production of ammonia itself.

"The greater the freedom from contamination the less apparent is the influence of the antiseptic upon the development of ammonia, and in a sample of exceptional purity spontaneous souring in the absence of preservative treatment appeared to inhibit the production of ammonia to a greater extent than did the addition of 3 per cent of chloroform or 0.1 per cent of formaldehyde."

A bacteriologic comparison of milk served in bottles and by the "dip" method, H. O. WAY (*Reprint from Cleveland Med. Jour.*, 1907, pp. 8).—Bacteriological examinations were made of bottled milk and milk dipped from cans in the ordinary way. The samples were obtained from 7 dealers in Cleveland, Ohio. Forty comparisons were made.

The milk dipped from cans was found to contain on an average 37 per cent more bacteria than the bottled milk. Eight samples of the dipped milk contained over 300 per cent more bacteria than the corresponding bottled samples. In 8 other comparisons the difference exceeded 50 per cent. Only 3 of the bottled samples contained over 50 per cent more bacteria than the dipped milk. The dipped milk contained a greater number of bacteria than 77.5 per cent of the samples examined. The bacterial content of the dipped milk as compared with that of the bottled milk was increased several hundred per cent by dry, windy weather.

Investigations on the action of rennet upon milk and feeding experiments with calves, F. PRYLEWSKY (*Milchz. Zentbl.*, 3 (1907), No. 3, pp. 81-113; *abs. in Rev. Gén. Lait*, 6 (1907), No. 7, pp. 165, 166).—The author discusses the nutritive value of milk and reports experiments in which various salts were added to boiled milk for the purpose of restoring the coagulability of the milk with rennet.

Sodium chlorid added in the proportion of 1 to 2 gm. per liter retarded coagulation but exercised a favorable influence on the curd. Calcium chlorid, 3 to 4 gm. per liter, accelerated coagulation and made a firmer curd than sodium chlorid. Trisodic citrate gave negative results. The tribasic citrates of calcium and magnesium produced the same effects as sodium and calcium chlorids. Sodium and potassium phosphates gave bad results. The three calcium phosphates gave favorable results but doubled the time required for coagulation. Calcium carbonate, 2 gm. per liter, hastened coagulation. An acid reaction rendered so by the development of lactic acid or the addition of hydrochloric acid was favorable to coagulation. A mixture of sodium chlorid, calcium chlorid, and hydrochloric acid, or of the calcium phosphates was more efficacious than the use of these substances singly.

The feeding experiments with calves showed that the addition of sodium chlorid was very advantageous, even when added to raw milk. Calcium chlorid and the monocalcic and tricalcic phosphates were not favorable to an increase in live weight.

In an experiment lasting 10 weeks, 3 calves were fed boiled milk to which 0.18 per cent of dicalcic phosphate had been added. Three were fed boiled milk containing 0.15 per cent tricalcic phosphate and 3 were fed raw milk preserved with formalin in the proportion of 1:10,000. The increase in live weight was greatest with the lot fed milk containing the tricalcic phosphate and least with the lot fed the milk preserved with formalin.

The experiments seem to indicate that boiled milk is not less favorable to the growth of calves than raw milk, and that in the case of boiled milk the addition of certain salts capable of restoring the power of the milk to coagulate with rennet may be made with advantage.

Development of factory dairying in Wisconsin, H. L. RUSSELL and U. S. BAER (*Wisconsin Sta. Rpt.* 1906, pp. 100-106, map 1).—This is a summary of Bulletin 140 of the station previously noted (E. S. R., 18, p. 770).

Apparatus for the simultaneous skimming of milk and the churning of the cream, O. KASDORF (*Rev. Gén. Lait*, 6 (1907), Nos. 6, pp. 122-130; 7, pp. 145-154; 8, pp. 169-179; 9, pp. 201-211, figs. 13).—The various forms of apparatus of this kind are described and illustrated.

Butter classification, M. A. O'CALLAGHAN (*Agr. Gaz. N. S. Wales*, 18 (1907), No. 3, pp. 223-227, pls. 4, fig. 1).—The author discusses the examination of butter for export, commenting upon the fishy flavor due to *Oidium lactis* and giving illustrations of numerous plate cultures of fish butters.

The water content of margarin, P. BUTTENBERG (*Ztschr. Untersuch. Nahr. u. Genussmitt.*, 13 (1907), No. 9, pp. 542-544).—The average water content of 148

samples of margarin from 18 factories was 14.90 per cent, the maximum 19.95 and the minimum 8.80. Of this number 105 contained more than 16 per cent.

Distribution of lactose-fermenting yeasts in dairy products, E. G. HASTINGS (*Wisconsin Sta. Rpt. 1906, pp. 107-115*).—The dairy products examined for the presence of lactose-fermenting yeasts included milk, whey, butter, and cheese. The yeasts were found to be widely distributed in Swiss, brick, and Cheddar cheese factories. They were also present in about one-fourth of the samples of butter examined and in 29 out of 51 samples of milk.

The main sources of infection are believed to be the soil proper and accumulations of dirt protected from drying. This type of yeast is not considered of economic importance except in certain branches of dairying. In Swiss and brick cheese factories infection with lactose-fermenting yeasts has, in several instances, caused considerable trouble. The danger from infection with this organism is not so apt to occur in Cheddar cheese making.

Milk, cream, butter, cheese, L. LINDET (*Rev. in Rev. Gén. Lait, 6 (1907), No. 9, pp. 211, 212*).—A chapter is devoted to each of the subjects in the title. The composition of milk, methods of analysis, and the principles and practice of butter making and cheese making are discussed.

Directions for making the Camembert type of cheese, T. ISSAJEFF (*Connecticut Storrs Sta. Bul. 46, pp. 57-75, figs. 10*).—The author describes the equipment necessary and gives detailed directions for making cheese of the Camembert type. The directions are based upon the research work which has been carried out by this Department in cooperation with the Connecticut Storrs Station during the last 3 years. Cheese of the Camembert type, considered equal in every way to the imported article, is now being manufactured at the station, the director of which announces in an introduction to the bulletin that the station is now prepared to assist factories and individuals in making this type of cheese.

Report of the congress of dairying, olive culture, and olive-oil industry, 1905 (*Cong. Licitaria, Olivicult. e Indus. Azcite 1905, Relat. Geral, I, pp. 764*).—This volume contains a number of reports relating to the dairy industry in Portugal. These deal with the raising of cows, sheep, and goats; the culture of forage crops; natural pastures; the production and sale of milk; manufacture and sale of butter, cheese, and condensed milk; construction of dairy buildings; cooperative dairy associations; agricultural credit in relation to the advancement of dairying and the olive industry; dairy schools and experiment stations; and the adulteration of milk and its products.

The microscopical examination of wine, A. BLAVIA (*Abonos Químicos, 7 (1907), No. 75, pp. 76-82, figs. 8*).—Notes are given on the microscopic examination of wines, the article being illustrated by figures showing crystals and the yeasts and other organisms commonly found.

Manufacture of vinegar from pure culture of acetic-acid bacteria, L. EBERLEIN (*Pure Products, 3 (1907), No. 4, pp. 173-177*).—The manner in which pure cultures of acetic-acid bacteria are used in vinegar making is described.

VETERINARY MEDICINE.

Report of the veterinarian, G. H. GLOVER (*Colorado Sta. Rpt. 1906, pp. 164-166*).—Particular attention has been given during the year to an investigation of loco weeds and horse typhoid. The results of these investigations will be published later. It appears that horse typhoid in Colorado is not due to parasitism with *Strongylus armatus*, but probably to infection with a blood parasite.

Regulations relating to animals' quarantine, 1907 (*Canad. Dept. Agr., Health of Animals Branch, 1907, pp. 16*).—The quarantine regulations of the Dominion of Canada are given in detail with definitions of terms used in the text and special accounts of the rules adopted for horses, mules, cattle, swine, and other animals. Orders Nos. 26-29 of the Minister of Agriculture relating to quarantine accompany the pamphlet.

Annual report of the State board of live stock commissioners of Ohio, T. L. CALVERT and P. FISCHER (*Ann. Rpt. Bd. Live Stock Comrs. Ohio, 5 (1906), pp. 43, figs. 13*).—The demand for the application of the tuberculin test has been greater than ever before. Considerable attention on the part of the board of commissioners has been given to sheep scab and glanders. Brief statements are given regarding the prevalence of anthrax, actinomycosis, foot rot of sheep, infectious hog diseases, nodule disease, mange in horses, and other infectious diseases. Copies are also given of laws relating to the inspection of live stock and the control of animal diseases in the State.

The incineration of animal bodies in a portable apparatus, J. C. E. LANGE (*Fortschr. Vet. Hyg., 4 (1907), No. 12, pp. 265-269, figs. 3*).—A comparatively inexpensive apparatus is described and illustrated consisting of a metallic cylinder mounted on wheels with a fire box underneath. The cylinder is of sufficient size to receive animal carcasses which are incinerated by the use of wood or other convenient fuel. The apparatus makes it possible to dispose of infectious animal bodies in a simple and convenient manner.

The sporulation of anthrax bacilli, R. EBERLE (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 2 (1907), No. 2-3, pp. 224-226*).—In a study of this question the author finds that gypsum sticks are well suited for use in sending material suspected of containing anthrax bacilli. Sporulation takes place readily upon the sticks of gypsum, but the process also requires the presence of oxygen and a certain moisture and temperature.

Transmission of pathogenic bacteria by the larvæ of worms, WEINBERG (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 4, pp. 203-205*).—From the studies carried out by the author it appears that the larvæ of worms in penetrating the intestinal mucous membrane are largely freed from pathogenic organisms which may have been attached to the surface of these parasites. These organisms are surrounded and destroyed by the phagocytes of the intestinal walls. In some cases, however, parasitic worms carry pathogenic bacteria through the intestinal wall, thus introducing the bacteria into the blood system or even into the subperitoneal tissues, where the parasitic worms become encysted.

Tumors in animals, CADOT (*Rec. Méd. Vét., 84 (1907), No. 3, pp. 87-103*).—The author discusses heredity, species, age, rations, traumatism, chronic inflammatory conditions, and infection as related to the development of cancerous tumors in various species of domestic animals.

A laboratory incubator, E. G. HASTINGS (*Wisconsin Sta. Rpt. 1906, pp. 116-119, fig. 1*).—On account of the expensiveness of bacteriological incubators, the author devised a simple means of installing one at a small cost. For this purpose an ordinary refrigerator was adapted to use for the bacteriological laboratory. The incubator with a regulator and heating apparatus was installed at a cost of \$80.

Tuberculosis work for 1905-6, H. L. RUSSELL and E. G. HASTINGS (*Wisconsin Sta. Rpt. 1906, pp. 91-99*).—The station officials have taken an active part in the detection and eradication of tuberculosis, especially among dairy cows. The tuberculin test has been applied on a large scale under an agreement that the owner shall discard for dairy purposes all reacting cattle.

A summary is presented of the results obtained by tuberculin tests since 1901. The percentage of reacting animals in these tests has varied from 2.7 to 19.7 and the number of animals annually tested from 182 to 5,781.

Tuberculosis in the light of recent literature, HEUSS (*Ztschr. Veterinärk., 19 (1907), No. 3, pp. 121-143*).—Some of the chief problems connected with the study of tuberculosis are stated and attention called to the wide variation of opinion which prevails on these points. It is believed that much study must be devoted to this disease before the controverted points will be established.

The chemical constitution of the tubercle bacillus, J. AUCLAIR and L. PARIS (*Compt. Rend. Acad. Sci. [Paris], 144 (1907), No. 5, pp. 278-281*).—The use of petroleum ether in extracting the fat from tubercle bacilli gave unsatisfactory results and the author, therefore, resorted to ether and chloroform. The experiments reported in this paper indicate that the acid resistance of the tubercle bacillus is not due exclusively to the fat or waxy material contained in the bacillus, but is a property of the body of the bacillus as a whole.

Behavior of pus cells toward tubercle bacilli, E. LÖWENSTEIN (*Ztschr. Hyg. u. Infektionskrank., 55 (1906), No. 3, pp. 429-450, pl. 1*).—It has long been observed that the leucocytes of animals affected with tuberculosis are capable of surrounding tubercle bacilli to a greater or less extent. At times, however, the leucocytes seem to lose this power. The author's observations were made on experimental animals and on pus cells obtained from the sputum of tuberculous human patients.

It appears from these experiments that the tubercle bacilli in a given tubercle acquire the power of resisting the leucocytes in that tubercle, and in general the same statement seems to be true for the tubercle bacilli present at any given time in the tuberculous animal. Such leucocytes, however, when removed from the body and mixed with material containing tubercle bacilli from some other animal show an active power in surrounding the bacilli. The author concludes, therefore, that tubercle bacilli have the power of gradually acquiring a resistance to the leucocytes with which they are more or less in constant contact.

A leather mask for use in the clinical diagnosis of bovine tuberculosis, L. OPALKA (*Ztschr. Infektionskrank. u. Hyg. Hausiere, 2 (1907), No. 2-3, pp. 227, 228, fig. 1*).—Considerable stress is laid on the possibility of clinical diagnosis of tuberculosis. For this purpose the respiratory sounds must be studied by auscultation. In order to increase the energy of respiration the nostrils are closed for a short time, and for this purpose a leather mask has been devised.

Nonreaction of tuberculous cattle to tuberculin, J. LIGNIÈRES (*Bull. Soc. Cent. Méd. Vét., 84 (1907), No. 4, pp. 90-112*).—Detailed clinical notes and post-mortem findings are given on a number of cases of tuberculosis in cattle which did not react to tuberculin. The author believes that this tolerance of tuberculin is perhaps of more frequent occurrence than has usually been suspected, and sometimes occurs in animals which show no clinical symptoms of the disease.

Infection with tuberculosis through the urachus, E. VAMOS (*Deut. Tierärztl. Wchenschr., 15 (1907), No. 5, pp. 63, 64*).—The evidence for transmission of tuberculosis through the essential reproductive cells is very slight, but a number of cases are known where the disease has been transmitted through the fetal membranes. Attention is called to these cases, and a detailed statement is given of a case in which infection took place in a calf through the umbilical cord.

The harmlessness of dust originating from desiccated tuberculous sputum, CADÉAC (*Jour. Méd. Vét. et Zootech., 58 (1907), Feb., pp. 65-71*).—After a series of experiments, during which animals were made to inhale or ingest

material containing tuberculous sputum, the author comes to the conclusion that such material is without virulence either for the respiratory or digestive organs. It is believed to be impossible to produce the disease by inhaling dust containing tuberculous sputum which has become desiccated without the influence of sunlight. It was shown by experiment that guinea pigs were not infected by eating 25 to 200 mg. of such material.

Tuberculosis in hogs without caseation or calcification, M. JUNACK (*Ztschr. Fleisch u. Milchhyg.*, 17 (1907), No. 5, pp. 164-171, figs. 2).—In a number of instances the author had occasion to observe tuberculosis in hogs in which the disease showed no tendency toward regression or natural limitation. The tubercles did not undergo caseation or calcification. On this account the author argues that in such cases of tuberculosis the whole carcass of the affected pig should be boiled or cooked by steam before admission for use as human food.

Vaccination against tuberculosis through the alimentary tract, J. NICOLAS (*Jour. Méd. Vét. et Zootech.*, 58 (1907), Jan., pp. 42-45).—This is a critical review of the experiments of Calmette, Guerin, Valkée, Roux, Arloing, and Stazzi. It has been found possible to produce an active immunity against tuberculosis by feeding animals tubercle bacilli of human origin, or bovine bacilli previously killed by heat or greatly attenuated. The immunity thus produced develops within a few months and is apparently of long duration.

Vaccination of cattle against tuberculosis, J. LIGNIÈRES (*Bul. Soc. Cent. Méd. Vét.*, 84 (1907), No. 4, pp. 112-125).—A record is given of 6 animals which were vaccinated against tuberculosis.

It appears from these and other experiments that tubercle bacilli which possess their full virulence have the power of producing the highest degree of immunity. The more tubercle bacilli used for vaccination are attenuated the weaker becomes the immunity. This is true without regard to the method adopted for attenuating the bacilli. From a sanitary standpoint it would be better if animals could be vaccinated against tuberculosis by the use of tubercle bacilli which could not multiply in the vaccinated animal. Immunity produced in this manner, however, is of short duration and of little value, and it is therefore necessary to use bacilli which possess some virulence. In no case, however, should vaccine be used from which the bacilli would remain alive for a long time in the tissues of the animal.

Combating tuberculosis on sewer farms, P. VINCEY (*Rev. Hyg. et Pol. Sanit.*, 29 (1907), No. 2, pp. 109-113).—The question having arisen regarding the possibility of danger to cattle from grazing on sewer farms, this matter was investigated with the result that the author discards the idea that forage grown on land irrigated with sewer water can carry tuberculosis to cattle. In case of an outbreak of the disease on such farms the usual method of procedure under other circumstances is recommended.

The etiology of milk fever, J. DE VRIES (*Tijdschr. Veeartsnijjk.*, 34 (1907), No. 5, pp. 310-318).—The literature of this subject is briefly reviewed for the purpose of citing cases in which milk fever has occurred without any connection with parturition. The etiology of the disease must still remain somewhat unclear since neither the theory of cerebral anemia nor that of the action of specific toxins thoroughly explains it.

Combating blackleg in Vogelsberg, A. SCHEIBEL (*Deut. Tierärztl. Wchnschr.*, 15 (1907), Nos. 5, pp. 61-63; 6, pp. 77-80, figs. 3).—The investigations reported in this paper were carried out on cattle and sheep. During a period of 5 years in which 3,200 cattle were vaccinated, only 3 were lost and the cause of death in these cases was not definitely determined. For the benefit of local practitioners, the author recommends that portions of the muscle tissue be saved from animals which die of blackleg in order to prepare vaccine from this

material. In vaccinating sheep, excellent results were obtained whether the vaccine was introduced in the tail or thigh.

An epizootic form of pneumonia caused by a new pasteurilla in sucking calves, J. LIGNIÈRES (*Bul. Soc. Cent. Méd. Vét., 84* (1907), No. 2, pp. 45-51).—A peculiar form of pneumonia prevailed among a herd of calves in Argentina. The disease appeared suddenly with a high fever and rapid respiration. The temperature usually rose above 40° C. and the majority of affected animals died. The lesions were largely confined to the thoracic cavity, which was filled with a reddish fluid. The pericardium and pleura were somewhat infiltrated and the lungs extensively hepatized. A peculiar form of pasteurilla was isolated from these cases and attempts were made to treat some of the affected animals with a polyvalent serum. The results were encouraging in mild cases, but only one serious case was cured by this method.

Treatment of gid in cattle, PROBST (*Wchuschr. Tierheilk. u. Viehzucht, 51* (1907), No. 8, pp. 141-143).—In ordinary cases there is considerable difficulty in locating the gid worm on the surface of the brain by the clinical symptoms of the infected animal. A description is given of a crude method adopted by an empiric, during which the position of the worm was determined by the sound obtained by tapping the forehead with a hammer. The skull was then trepanned and the gid worm removed. The animal recovered within a reasonable time.

Acute mastitis with fatal results following foot-and-mouth disease, G. P. MORETTI (*Clin. Vet. [Milan], 30* (1907), No. 10, pp. 145-147).—Notes are given on the clinical symptoms in two cases of acute mastitis which appeared during the course of foot-and-mouth disease. Injections of a 5 per cent solution of creolin were made in the udder and caffein was also administered without much beneficial effect.

Sheep scab and enzootic ophthalmia, F. W. GARNETT (*Vet. Rec., 19* (1907), No. 973, p. 554).—Carbolic dip had been used in double strength on a herd of sheep infected with scab. When the author examined this herd of sheep a number of cases of ophthalmia were observed, which were at first supposed to be due to the irritating effect of the dip. This was found, however, not to be the case, from which it appears that troubles of this sort may sometimes wrongly be attributed to the action of the dip.

Creosote as a remedy for parasitic gastritis in sheep, H. TAYLOR (*Vet. Rec., 19* (1907), No. 979, p. 492).—A flock of sheep became badly infested with *Strongylus contortus* and the author tested the value of creosote in combating these parasitic worms. A 1 per cent solution of coal-tar creosote in water was prepared and each sheep was given 4 oz. of this solution. Previous to the use of the creosote the sheep had been dying at frequent intervals from the effects of the stomach worm, but after drenching with creosote no deaths occurred during a period of 12 months, after which the history of the sheep was not followed.

Saccharomycosis in the nostrils resembling glanders, G. MARCONE (*Rev. Gén. Méd. Vét., 9* (1907), No. 101, pp. 249-253).—An opportunity was had to study lesions produced by *Saccharomyces equi* in the horses belonging to a regiment of artillery. Symptoms developed which closely resembled those of glanders, including a nasal discharge, swelling of the submaxillary glands, and ulcerations of the skin. A microscopic examination of the nasal discharge, however, at once disclosed the nature of the disease.

A report on pneumonia in army horses, LUDWIG (*Ztschr. Veterinärk., 19* (1907), No. 2, pp. 49-66).—Extended observations showed that the majority of horses which recover from this disease are thereafter immune. Notes are given

on the prevalence of pneumonia and the regulations which have been adopted for controlling the disease, including quarantine and compulsory infection.

Pernicious anemia of the horse, H. CARRÉ and H. VALLÉE (*Rev. Gén. Méd. Vét.*, 8 (1906), No. 95, pp. 593-608, figs. 4; 9 (1907), No. 99, pp. 113-124, figs. 4).—According to the authors' experience, acute cases of this disease are absolutely incurable. In some instances improvement is noted as a result of high feeding and the use of tonics, but such improvement is more apparent than real. Immunization has not proved successful by the means thus far adopted, but further experiments along this line will be carried out. The disease is transmitted through the digestive tract and the excretions of diseased animals are virulent for some time. This suggests a practical means of checking the prevalence of the disease.

Equine malaria, F. A. VERNEY (*Natal Agr. Jour. and Min. Rec.*, 10 (1907), No. 1, pp. 1-5).—The post-mortem changes produced by this disease are briefly described. It may be cured in a large percentage of cases if Epsom salts, nitre, and quinin are given in large quantities at the outset. Equine malaria is probably carried by ticks, although this has not been definitely established.

Swamp fever in horses, L. VAN ES (*North Dakota Sta. Rpt.*, 1906, pt. 1, pp. 48-65, pls. 6).—For a number of years a form of anemia has been observed in horses in Minnesota, the Dakotas, and Manitoba, and has usually been referred to as swamp fever. It has caused considerable losses in infected localities. Recently a disease appeared among horses in the Red River Valley and appeared to be identical with swamp fever. A careful study was made of this disease from the clinical symptoms and autopsies, and the observations made along this line are compared with those recorded from studies of the disease in other localities. The work thus far carried on has not led to a definite conclusion regarding the etiology of the disease. The symptoms and pathological lesions are fairly constant and a variety of parasites and bacterial organisms were found in affected animals. None of these, however, has been shown to be the cause of the disease.

The treatment of dourine, V. L. YAKIMOV (*Arch. Vét. Nauk [St. Petersburg]*, 36 (1906), No. 12, pp. 975-986).—A series of experiments was carried on with mice, guinea pigs, rabbits, and dogs during which trypanrot was used to test its value in the treatment of experimental dourine.

It is found that trypanrot shows a specific action in the treatment of dourine. Doses of 0.5 cc. of a 1 per cent solution are capable of causing the trypanosomes to disappear from the blood of mice if introduced within 5 days after the animal has been inoculated. This treatment, however, does not prevent an occasional relapse. Trypanrot was found to possess a very limited prophylactic value, but when used within from 5 to 9 days after inoculation it will prevent fatal results. In guinea pigs it exercises a toxic effect. When administered in hypodermic injections in the proper strength of solution, trypanrot causes no bad effect in white mice or gray rats, but in guinea pigs, rabbits, and dogs it produces an inflammation of the adjoining tissue.

A little recognized cause of colic in the horse, H. MOLLEREAU (*Rev. Gén. Méd. Vét.*, 9 (1907), No. 101, pp. 241-249).—The causes commonly recognized for colic in the horse are usually operative in cases of this disease. The author, however, had opportunity to study an outbreak of colic among cavalry horses which received water contaminated from sewage and carrying typhoid bacilli. When these organisms were present in large numbers, digestive disturbances were observed in the horses, under a form which could scarcely be distinguished from colic. In the author's opinion more attention should be given to the quality of water which horses receive.

Further experiments on the filterability of the virus of swine plague and hog cholera. R. OSTERTAG and A. STADIE (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 2 (1907), No. 2-3, pp. 113-117).—Six inoculation experiments were carried out with filtered virus obtained from hogs affected with swine plague. It was found that the disease could not be transmitted in this way. With hog cholera, however, results were different. In 5 out of 8 cases the disease was transmitted by the use of filtered virus. The authors conclude, therefore, that Schweinepest of Germany, like hog cholera in this country, is caused by a filterable virus and that *Bacillus suispestifer* becomes subsequently established in the lesions.

The Swedish regulations regarding infectious swine diseases. A. PETERSEN (*Veröffentl. K. Gsundhetsaml.*, 31 (1907), No. 10, pp. 231-237).—Copies are given of the most recent proclamations of the Swedish government regarding measures for the control of hog cholera, swine plague, and swine erysipelas.

The etiology of rabies. P. REMLINGER (*Compt. Rend. Soc. Biol. [Paris]*, 62 (1907), No. 6, pp. 249, 250).—On the basis of his experience the author maintains that in more than 50 per cent of cases rabies virus introduced into animals or human beings will make its way along the nerves or through tissues and produce the usual symptoms of rabies.

Diagnosis of rabies in laboratories. LENTZ (*Fortschr. Vet. Hyg.*, 1 (1907), No. 12, pp. 269-275).—In the author's experience the identification of Negri's corpuscles furnishes a reliable and satisfactory means of diagnosing cases of rabies. As a rule, rabbits inoculated with virulent virus show symptoms of the disease within from 13 to 21 days. This inoculation test may be resorted to in cases where diagnosis by Negri's corpuscles is impossible.

Negri's corpuscles in fixed virus. B. V. FURSENKO (*Arch. Vet. Nauk [St. Petersb.]*, 36 (1906), No. 10, pp. 735-739).—As a result of the microscopic study of Negri's corpuscles, the author comes to the conclusion that complete evidence regarding the etiological significance of these bodies can not be developed until improved methods are devised for the study of their structure.

Immunization against fowl cholera, hemorrhagic septicemia, and swine plague with bacterial extracts. J. CITROX and R. PÜRZ (*Ztschr. Hyg. u. Infektionskrank.*, 56 (1907), No. 1, pp. 145-174, pl. 1).—The bacterial extracts with which the experiments reported in this paper were carried on are identical with the artificial aggressins of Wassermann. In the preliminary experiments it was found that rabbits could be thoroughly immunized against fowl cholera by the use of bacterial extracts obtained from serum. These results are attributed to artificial rather than to natural aggressins. Immunization is more easily accomplished in rabbits than in pigeons. By means of artificial aggressins similar satisfactory results were obtained in the case of hemorrhagic septicemia and swine plague. It is held, however, that while the organisms of these three kinds of septicemia behave in a very similar manner this fact can not be used as proof of their identity.

The virus of fowl plague. V. K. RUSS (*Arch. Hyg.*, 59 (1906), No. 1, pp. 286-312).—The blood from cases of this disease is exceedingly virulent, being fatal when used in such extreme dilution as 1:1,000,000,000. The micro-organism of the disease appears to be in some way attached to the blood corpuscles or in some cases to wander into these structures. In a centrifugal machine, the virus of fowl plague may be partly separated from the blood corpuscles and serum, although no complete sterilization of any part of the material can be accomplished in this way. Notes are given on the effect of various chemicals upon the virus of the disease.

An attempt was made to produce active immunity by the use of the virus

killed by high temperature. The experiments along this line fail to give satisfactory results and indicate that immunity can not be brought about by the method in question.

Fowl plague, C. DEPPERICH (*Fortschr. Vet. Hyg.*, $\frac{1}{4}$ (1907), No. 10, pp. 217-226; *II*, pp. 241-250).—A number of experiments were made in artificial inoculation with this disease. The literature of this subject is critically reviewed and notes are given on the commonly observed pathology. It has been impossible thus far to demonstrate the micro-organism of the disease, but all experiments indicate that it is ultra-microscopic in size.

The use of diphtheria antitoxin in the treatment of roup, BATTIER (*Compt. Rend. Soc. Biol. [Paris]*, 61 (1906), No. 37, pp. 605, 606).—In an outbreak of roup among fowls the author tested diphtheria antitoxin such as is used in human cases of this disease. The results were very satisfactory in all cases. The dose used was 1 cc. The author was able by this means not only to check the spread of the disease, but to bring about a cure in affected birds. These experiments raise again the question regarding the possible relationship between roup and human diphtheria.

RURAL ENGINEERING.

Small reservoirs in Wyoming, Montana, and South Dakota, F. C. HERRMANN (*U. S. Dept. Agr., Office Expt. Stns. Bul.* 179, pp. 100, pls. 8, figs. 13).—A large area of the arid land in the Western States can only be reclaimed by comparatively small irrigation plants erected by settlers with limited means and making use of the small torrential streams, which are dry a greater part of the year. These small systems must include reservoirs of capacity sufficiently large to accumulate as much as possible of the flood flow of the stream and in many instances their proper construction requires greater engineering skill and attention than can be given by the settlers or county surveyor. Many small reservoirs are now planned or under construction to fulfill the requirements of the Desert Land Act and the settlers undertaking these constructions are in need of professional advice which their restricted means and the remoteness of the work prevent their securing. The author has therefore undertaken to provide a manual for such settlers, and in critically discussing existing reservoirs and the problems connected with reservoir construction offers many suggestions which should be helpful to them.

A large number of small reservoirs in northeastern Wyoming, western South Dakota, and southeastern Montana were personally visited by the writer, and each reservoir is discussed from the standpoint of construction and cost, defects where existing being pointed out, and the profits accruing through the use of stored water being given where data could be secured. The most obvious defect in the reservoirs visited was a lack of ample wasteway capacity, and in the light of this fact the author develops a method of computing the size of wasteway based upon the intensities of storms likely to be found on the watersheds of the reservoirs in the section considered.

From records of the Weather Bureau diagrams are drawn showing the intensities of storms of different lengths and the run-off for a factor of 25 per cent, although it is stated that "with the catchment area well saturated it varies from about 18 per cent for the 2-hour storms to about 30 per cent for 5-minute storms, though this variation is not uniform." From this data a concrete case is cited and the necessary capacity of the wasteway is determined, the example illustrating the great importance of the effect of short but severe storms which frequently occur in the locality under discussion.

The design and construction of dams and wasteways suitable for small reser-

voirs is taken up in some detail, the form, material, and methods of construction being considered. From his investigations the author concludes that while in the district in question cattle and stock raising must remain the chief industry, yet the system of continuous ranging must eventually be abandoned and the range supplemented by the farm, which will be irrigated by the flood waters of small streams conserved in reservoirs. The annual outlay in farming 60 acres, including the interest on the reservoir and irrigation plant and the cost of cultivation of the land, is placed at \$470, while from the products grown upon this area it should be possible to maintain during the winter 1,200 head of sheep, which should bring in an annual return of \$900, leaving a net profit of \$430 from winter feeding.

Evaporation losses in irrigation and water requirements of crops, S. FORTIER (*U. S. Dept. Agr., Office Expt. Stas. Bul. 177, pp. 64, pls. 2, figs. 19*).—This bulletin reports the results of investigations which have been carried on for a number of years by this Office in cooperation with the State of California to determine not only the evaporation losses in irrigation, but also the remedies which will lessen these losses. Experiments were conducted in water-jacketed tanks under field conditions in the following localities: Tulare, Pomona, Berkeley, Chico, and Riverside. Evaporation losses were determined by weighing the tanks, various methods of application of the water and various systems of cultivation and mulching being studied. From these experiments it was found that the conditions having greatest influence on evaporation from soils are the quantity of water in the top soil, the temperature of the soil and water, and the wind movement. The application of water at a depth of 3 in. or more was found to subject it to a much reduced soil temperature and thereby lessened evaporation, while cultivation after irrigation has the same effect, since loose earth is a poor conductor of heat. Reduction of the temperature of the water was found to be equally productive of economy, a reduction of 7° in temperature, decreasing evaporation from a water surface by 0.1 in. per day, which points to the possibilities of saving by applying water at night when the surface soil is cool, or by applying it at sufficient depths to keep it from coming in contact with the hot surface layer of soil.

The experiments which have a direct bearing on present irrigation practice are those testing the effects of cultivation after irrigation and applying water in furrows of different depths. The saving in a 6-day period by cultivation in one case was 6.25 per cent of water applied and in another experiment, where less water was applied, the saving in a 3-day period was 2.38 per cent of the water applied. The maximum saving shown by the furrow experiments was 9.23 per cent of the amount applied, the experiments covering 10 days.

Another point forcibly brought out by the experiments is the large loss when water is applied in frequent light irrigations, which keep the water always exposed to the conditions causing the largest evaporation.

In the experiments on water requirements of crops, it was found that for conditions similar to those at Tulare 18 to 24 in. is the best amount of water to use in the irrigation of wheat, while barley was found to have about the same water requirements. Horse beans grown at Berkeley were found to give crops increasing with the amount applied up to the maximum used of 38 in.

Arterial drainage in Ireland (*Engineer [London], 103 (1907), No. 2677, p. 394*).—A commission appointed in 1905 to inquire into matters bearing on the arterial drainage of Ireland has recently issued its report, which comprises various points of general interest.

After reviewing the several drainage acts which have been passed from time to time and which have largely become inoperative, due to the unsettled condition of land tenure and unequal or impossible distribution of benefits,

the commissioners are of the opinion that it is essential to repeal all existing drainage acts and to pass a new one suited to existing conditions. It is proposed that this act shall provide "for the initiation, execution, and maintenance of new districts as well as for the maintenance of existing ones." It contemplates bringing into harmonious working a drainage department, the county councils and the rural councils, as well as the individuals to be directly benefited. The organization is so designed, since many small districts could be drained and improved at small cost without much engineering difficulty and the assents of the proprietors could be easily obtained, while the increased value of the land would repay the outlay. On the other hand, there are large works presenting serious engineering difficulties and involving heavy expenditure. Where such works are to be undertaken an excess of the actual over the estimated cost must be contemplated, and the difficulty of securing the assents of the proprietors to the scheme would be correspondingly increased. The security for the repayment of the loan would also have to be considered. Finally the large works, such as the improvement of the outfalls of large rivers, being admittedly of unproductive nature, but absolutely essential, would, if done at all, have to be assisted by the State by means of free grants.

The commission recommends that in many instances outfall works should be designed to meet the ordinary annual floods instead of providing works capable of taking care of exceptional floods which occur at intervals of perhaps 20 years, and thereby saving considerable in the first cost.

The report describes the constitution and powers of the proposed administrative bodies and deals with the financial considerations involved. It is recommended that government loans for arterial drainage should be made direct to the county councils, the councils recovering the due proportion of the annual installment from each landholder by means of the "poor rate." Further, the commissioners are of the opinion that it would be injudicious as well as unjust to levy a pro ratum assessment on the entire catchment basin for the purpose of drainage, but that the cost should be borne by the land actually drained and improved.

Portable hog houses, J. G. FULLER (*Wisconsin Sta. Rpt. 1906, pp. 42-46, figs. 2*).—Describes method of construction and gives material necessary for a small portable cot costing complete about \$12.50.

Farm implement investigation, C. A. OCOCK (*Wisconsin Sta. Rpt. 1906, pp. 285-287*).—Gives information in tabular form as to the number of farm machines used by the Wisconsin farmer and an idea of the care given these machines.

RURAL ECONOMICS.

Cyclopedia of American agriculture. Farms, L. H. BAILEY ET AL. (*New York: The Macmillan Co., 1907, vol. 1, pp. XVIII+648, pts. 25, figs. 756*).—This volume is the first of a contemplated series of four volumes and is a popular survey of agricultural conditions, practices, and ideals in the United States and Canada. It consists of four parts dealing, respectively, with the agricultural regions, the projecting of a farm, the soil environment, and the atmospheric environment. On these topics a great storehouse of available information is presented.

Report of the Irish Agricultural Organization Society, Limited, N. T. EVERARD and R. A. ANDERSON. (*Rpt. Irish Agr. Organ. Soc., 1906, pp. 136*).—Detailed statistical data and discussions of the work of the affiliated organizations for the year ended June 30, 1906. There was a net gain over the preceding year of 60 societies, of which 32 were credit societies or cooperative banks and 18 agricultural societies for the purchase of farm supplies.

Agricultural credit, F. PASQUELLE (*Semaine Agr. [Paris]*, 26 (1907), No. 1354, pp. 133, 134).—The author discusses the relation of local agricultural credit banks to the district banks, the organization of credit banks, how farmers are admitted to membership and secure loans, the rates of interest paid on loans, and other matters relating to the organization and administration of agricultural credit banks in France.

Agricultural settlements (*Bol. Sec. Fomento [Mexico]*, 6 (1907), No. 7, pp. 244-255).—This article reviews the methods of establishing and directing small agricultural holdings in the neighborhood of cities and in industrial centers of France, Germany, England, Belgium, and Sweden for the purpose of providing work for the city unemployed and of interesting industrial workers in agricultural pursuits. The beneficial results of this movement from the economic, moral, and financial points of view are especially commended.

The purpose of the article was to call attention to agrarian conditions in Chile, where the land is said to be held by a few people. As a result, hostility prevails between proprietors and workers, the rural districts are being depopulated, pauperism increases in the cities, and the most vigorous portion of the population emigrates from the country. The adoption of the European system of breaking up large estates into small holdings and the governmental encouragement of land settlement by providing land, seed, implements, fertilizers, etc., to reliable settlers under easy terms are advocated for the improvement of economic conditions in Chile.

The article is reprinted in the above publication because its teachings are said to be equally applicable to Mexico at the present time.

Agricultural cooperation, R. PAISANT (*Semaine Agr. [Paris]*, 26 (1907), No. 1354, pp. 132, 133).—A discussion of the law of December 29, 1906, regulating the control of the 40,000,000 francs set aside by the French government for the aid of agricultural cooperation, with special reference to the disposition of the fund, methods of securing loans, and the importance of the movement to French agriculture.

The international cooperative movement in agriculture, M. PAISANT (*Bul. Soc. Nat. Agr. France*, 67 (1907), No. 2, pp. 168-176).—The author discusses the tendency of the movement in agricultural cooperation to pass beyond national boundaries, and briefly outlines the history to date of several international organizations whose aim it is to make world-wide the prosperity of agriculture.

The competitive ability of large, medium, and small size farming, J. HOCH (*Landw. Jahrb.*, 36 (1907), No. 1, pp. 1-97).—A detailed critical discussion of this subject in which it is shown in general that small and medium-size operations are economically superior to farming on a large scale. This advantage, however, is due not so much to the district in which the farm lies nor to special methods of culture as to the greater productivity of a uniform soil and of the industry as a whole.

Agricultural bank act amendments (*Jour. Dept. Agr. West. Aust.*, 15 (1907), No. 2, pp. 124-126).—The expansion of the agricultural industry in Western Australia from 73,408 acres under cultivation in 1890 to 364,704 acres in 1906 is attributed in great measure to the establishment of the agricultural bank system.

Under the law and its amendments which went into effect on February 1, 1907, £1,000,000 is now made available to borrowers on farm property at 5 per cent interest. The conditions under which sums may be borrowed and repaid, as well as the care of the property, are enumerated. For the first five years interest only is collected, but at the expiration of that time regular installments of principal and interest become payable semiannually for 25 years, or sooner at

the option of the borrower. The improvement of holdings under the present law as a means of affording employment to persons out of work in commercial centers is urged upon the agricultural property holders of Western Australia.

Report of the departmental committee on small holdings in Great Britain, EARL OF ONSLOW ET AL. (*London: Govt., 1906, pts. 1, pp. III + 61; 2, pp. VIII + 542*).—Part 1 contains the report of the committee with recommendations, and part 2 the minutes of evidence and 27 appendixes relating to agricultural holdings in Great Britain and other countries. The recommendations of the committee have been noted from another source (E. S. R., 18, p. 885).

Agriculture in Japan, E. THÉRY (*Écon. Européen, 31 (1907), No. 793, pp. 359-361*).—This is a discussion of the present condition of agriculture in Japan, the improvement that has taken place since 1895, and the interest taken by the government in promoting agriculture by means of experiment stations, agricultural credit banks, and cooperative societies.

Statistics are given relating to the production and exportation of camphor and lacquer, the number of cattle, horses, sheep, goats, and pigs, the extent of the fish and silk industries, and the use of commercial fertilizers. More than 60 per cent of the population of Japan are engaged in agricultural pursuits, and in 1900 3,338,600 were engaged in the fish industry. A large quantity of fish is used as fertilizer, but latterly large importations of commercial fertilizers from the United States, Chile, and England are being utilized. The value of these imports in 1905 was 57,195,552 francs. The wages of farm help have increased 70 per cent since 1895.

Agricultural production in Japan, R. GONNARD (*Rev. Écon. Internat., 2 (1907), No. 1, pp. 136-162*).—An article similar in scope to the above, but with more detailed discussion of the extent of cultivated and uncultivated land, forests, food and industrial products, stock raising, fishing and fish culture, and particularly the extent of recent legislation in behalf of agriculture in Japan.

Twenty-second statistical report of the department of agriculture and commerce, Japan, B. KURÉ (*Statist. Rpt. Dept. Agr. and Com. Japan, 22 [1906], pp. XII + 644, maps 3*).—Detailed statistical data on the production, exportation, and importation of agricultural products for the year 1906, together with other statistics on the commerce, industries, fisheries, mining, forests, etc., of Japan.

Crop Reporter (*U. S. Dept. Agr., Bur. Statist. Crop Reporter, 9 (1907), No. 5, pp. 33-40*).—Statistics and notes on the condition of crops and the supplies, value, and prices of agricultural products in the United States and foreign countries are summarized.

The ninth biennial report of the commissioner of agriculture, State of Florida, B. E. MCLIN (*Bien. Rpt. Comr. Agr. Fla., 9 (1905-6), pp. VII + 647*).—This report for the years 1905 and 1906 contains detailed agricultural statistics for 1904 and 1905, commercial statistics for 1905 and 1906, meteorological data for 1905, reports of the fertilizer and stock feed, prison, and land departments, general statistics from the State census of 1905, and a report by the chemist for 1905 and 1906.

Annual statistical and crop report of Louisiana for the year 1906, C. SCHULER (*Ann. Statist. and Crop Rpt. La., 1906, pp. 12*).—The acreage, yields, and value of the principal farm crops are summarized, with data on the agricultural and other industries of the State. A special article by W. Newell gives the results of nursery inspection in Louisiana since 1905.

Annual statistical report of the New York Produce Exchange for the year 1906, with comparisons with preceding years (*Ann. Statist. Rpt. N. Y. Produce Ex., 1906, pp. 177*).—Tabulated statistical data on the production, shipments, and prices of staple agricultural products in the United States.

Agricultural statistics [of Argentina] for 1906 (*Estad. Agr. [Argentina], 1906*, pp. 59, fig. 1).—Tabulated data relating to the acreage under crops, the production, exportation, importation, and prices of farm products, including live stock and meat, for the year 1906 in comparison with preceding years are reported.

Agricultural and live stock statistics for the year ending March 31, 1906, with prefatory report, L. H. SHOLL (*Agr. and Live Stock Statis. So. Aust., 1906*, pp. XVIII + 91).—Detailed statistical data of land occupation, acreage and yields of crops, number of live stock, etc. The prefatory report discusses these statistics in comparison with similar data for preceding years to show the progress made in the agricultural industry of South Australia during the past decade. The methods of securing the data as strictly confidential government property are also explained.

Agricultural statistics, Ireland, 1906 (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis. 1906*, pp. 41).—The data are more detailed and in revision of those previously noted (E. S. R., 18, p. 788).

Summary of agricultural statistics for the years 1901 to 1905 (*Bul. Agr. [Brussels], 22 (1906), No. 7, pp. 999-1055*).—Tabulated data for each province of Belgium of the acreage and yields of crops, the utilization of commercial fertilizers and feeding stuffs, the number of live stock, and the number and size of farm holdings. The farms increased from 277,754 in 1901 to 296,314 in 1905, with 1,707,696 and 1,761,757 hectares under cultivation, respectively.

AGRICULTURAL EDUCATION.

Agricultural education in England, J. C. MEDD (*Nineteenth Cent. and After, 1907, No. 359, pp. 108-118*).—This is a critical discussion of the shortcomings of agricultural education in England, the causes of which are attributed mainly to lack of system and central direction.

Agricultural instruction of collegiate grade is said to be fairly well provided for, but the great shortcoming is the "scanty provision of facilities for intermediate agricultural education of a systematic character," such as would "provide for the sons of small farmers from 13 or 14 to 16 or 17 years of age." Schools similar to the higher elementary schools in France and winter schools of agriculture and horticulture similar to those in Holland are recommended.

The writer believes that the term "agricultural" should not be applied to instruction in the public schools owing to the general misunderstanding which arises and the discredit into which the subject consequently falls. He would apply the term "rural science" or "nature study" to this class of teaching. He demands for the country boy as thorough an elementary education as the town boy has, and recommends a differentiation between rural and village schools not by means of any fundamental change in their respective curricula, but by the different treatment of the subjects and "their orientation toward the immediate and varying surroundings of each school."

The fundamentals of farming, C. D. SMITH (*Country Gent., 71 (1906), Nos. 2807, p. 1061; 2808, pp. 1085, 1086; 2809, p. 1109; 2810, pp. 1133, 1134; 2811, p. 1157; 2812, p. 1181; 2813, p. 1205; 72 (1907), Nos. 2814, pp. 5, 6; 2815, p. 29; 2816, pp. 53, 54*).—The titles of these papers are as follows: (1) The vacant space in soils, (2) the structure of the soils, (3) water as a solvent, (4) the movement of water in soils, (5) preventing losses of soil water, (6) the formation of humus, (7) water and air in soils, (8) soil temperatures—chemistry, (9) getting nitrogen into the soil, and (10) nitrogen and other elements.

The growing importance of plant physiology in agricultural education, C. E. BESSEY (*Lincoln, Nebr.: 1906, pp. 5*).—An address before the Society for the Promotion of Agricultural Science, in which the evolution of botany teaching is traced and the importance of a thorough knowledge of plant physiology to the plant pathologist, the plant breeder, and the scientific agronomist is emphasized.

The farm mechanics laboratory in higher agricultural schools, A. LONAY (*Ann. Gembloux, 17 (1907), No. 2, pp. 95-98*).—An argument for the establishment of farm mechanics laboratories in the higher agricultural institutions of learning.

Foreign schools of home economics and their creation in France, L. HENRY (*Bul. Mens. Off. Renseign. Agr. [Paris], 6 (1907), Nos. 1, pp. 42-65; 2, pp. 173-191; 3, pp. 323-345*).—This is a report to the Minister of Agriculture by Professor Henry of the National School of Horticulture at Versailles, who in preparation for this work visited many of the schools and colleges for women in Belgium, Switzerland, and other countries.

The first part of the report is taken up with a discussion of the necessity for special instruction for farmers' daughters, in which it is pointed out that in this respect France compares very unfavorably with Belgium, Germany, Austria, England, and North America.

A project for the organization of instruction in agriculture and domestic economy for the daughters of farmers is outlined. The establishment of three types of schools is recommended: (1) Complementary and professional agricultural schools, (2) schools of agricultural home economics, and (3) temporary and movable schools of agricultural home economics.

The first type of school corresponds somewhat nearly to the practical schools of agriculture for boys in France except that the studies are to be of higher grade and less varied. They are to be elementary finishing schools for farmers' daughters, with a regular course of study covering 2 years and a supplementary elective course of 1 year. The subjects to be included in the course of study are pedagogy, French, arithmetic, farm accounts, history, geography, the natural and physical sciences, drawing, and hygiene. The natural sciences will include botany, geology, mineralogy, and zoology, but special attention will be given to domestic economy, horticulture, dairying, poultry culture, and animal husbandry. The report outlines in considerable detail the proposed course of study and the organization and equipment of the schools. This type of school is considered the most important and the one to be most generally established.

The proposed schools of agricultural home economics correspond to the farm schools for boys in France. There are already 3 such schools, 2 known as dairy schools, and 1 as a school of agricultural home economics and dairying.

The third type of school is the temporary or movable school of agricultural home economics, corresponding somewhat closely to the winter schools of agriculture in Germany. It is suggested that after these 3 types of schools are established it would be well to inaugurate one or two superior schools of agricultural home economics corresponding to the national schools of agriculture for young men.

After outlining at some length his project for instruction in home economics in France, the writer describes the various schools and other agencies for the education of young women along lines of agriculture and home economics in Belgium, the Grand Duchy of Luxembourg, Alsace-Lorraine, and Switzerland. He also gives a list of schools for young women in Germany not mentioned in his description.

The established principles of nature study, M. A. BIGELOW (*Nature-Study Rev.*, 3 (1907), No. 1, pp. 1-7).—The writer contends that there is now general agreement among authorities and leading teachers concerning (1) the working definition of nature study, (2) its differentiation from science in the strict sense, (3) the aims of nature study for elementary education, (4) the fundamental nature of the observational method, (5) the principle governing selection of materials for nature study, and (6) the dependence of nature study on child study.

Nature study is defined as "the simple observational study of common natural objects and processes for the sake of personal acquaintance with the things which appeal to human interest directly," and the author proceeds to harmonize this definition with the views of Professors Hodge and Bailey on this subject. Contrasting nature study with elementary science, the writer takes the position that the former is for the sake of personal acquaintance with the things which appeal to human interest directly and independently of their relations to organized science, while the latter is the "close analytical and synthetical study of natural objects and processes primarily for the sake of obtaining knowledge of the general principles which constitute the foundations of modern science." Nature study should lead up to and into the study of science.

The values of nature study are said to be in discipline and information. The aims are to give general acquaintance with and interest in common objects and processes in nature, to give first training in accurate observing, and to give pupils useful knowledge concerning natural objects and processes as they directly affect human life and interests. Concerning the "dependence of nature study on child study," the writer contends that we must recognize the fact that there is a difference between nature study for children and nature study for adult minds.

Suggestions for conducting community gardens, SUSAN B. SIPE (*Atlantic Ed. Jour.*, 2 (1907), No. 9, pp. 22-24, figs. 5).—These are suggestions based on the experience of the writer in conducting children's gardens in Washington, D. C., and include answers to many troublesome little problems that have hitherto confronted the teacher of school gardening, such, for example, as the size of plats, the nature of the preliminary instruction, the plan of the gardens, and the correlation of gardening with other subjects and its adaptation to country school conditions.

Course in fruit growing for movable schools of agriculture, S. B. GREEN (*U. S. Dept. Agr., Office Expt. Stas. Bul. 178, pp. 100*).—This is the second in the series of bulletins for movable schools of agriculture. It includes general suggestions to teachers and a syllabus of 15 lectures, each of which is supplemented by suggestions for experiment and practice work. The lectures cover general discussions on the factors that make up a good fruit-growing section, cultivation and cover crops, the use of fertilizers, varieties, planting, pruning, orchard protection, harvesting, marketing, storing, botany of cultivated fruit plants, propagation of fruit plants, and specific cultural directions for the apple, pear, quince, peach, nectarine, plum, apricot, cherry, grape, and several small fruits. Lists of references, apparatus, and material are appended.

Organization lists of the agricultural colleges and experiment stations in the United States (*U. S. Dept. Agr., Office Expt. Stas. Bul. 176, pp. 100*).

University of Tennessee. Relations of the University to the State (*Univ. Tenn. Rec.*, 10 (1907), No. 2, pp. 65).—This is a report by a special committee of the board of trustees of the University of Tennessee appointed to inquire into the exact relationship under its charter of the University of Tennessee to

the State. The report goes back to the origin of Blount College in 1794. This institution was subsequently turned over to East Tennessee College, later known as East Tennessee University, and after 1879 as the University of Tennessee.

The social rôle of the farmer's wife, P. DE VUYST (*Le Rôle Social de la Fermière. Brussels: Librairie Albert Dewit, 1907, pp. 184*).—This is a valuable compilation of information concerning the professional training of farmers' wives and some of the agencies concerned in this work, including domestic science associations, reading circles, women's institutes, and definitely organized courses of instruction in schools in Germany, Austria, Luxembourg, France, Russia, Scandinavia, Switzerland, the United States, and Canada.

MISCELLANEOUS.

Annual Reports of the Department of Agriculture, 1906 (*U. S. Dept. Agr. Rpts. 1906, pp. 698*).—This is made up of the reports of the Secretary and heads of Bureaus. The various reports are also issued as separates.

Nineteenth Annual Report of Colorado Station, 1906 (*Colorado Sta. Rpt. 1906, pp. 109-170*).—This contains the organization list, a report of the director, departmental reports, and a financial statement for the fiscal year ended June 30, 1906.

Fifteenth Annual Report of Delaware Station, 1903 (*Delaware Sta. Rpt. 1903, pp. 172*).—This contains a financial statement for the fiscal year ended June 30, 1903, and reports of the heads of departments containing numerous articles which are abstracted elsewhere in this issue.

Annual Report of Idaho Station, 1906 (*Idaho Sta. Rpt. 1906, pp. 40*).—This contains the financial statement for the fiscal year ended June 30, 1906, a report of the director, and departmental reports one of which is abstracted elsewhere in this issue.

Twentieth Annual Report of Nebraska Station, 1906 (*Nebraska Sta. Rpt. 1906, pp. 16*).—This contains the organization list, a review of the work of the station during the year, and a financial statement for the fiscal year ended June 30, 1906.

Seventeenth Annual Report of North Dakota Station, 1906 (*North Dakota Sta. Rpt. 1906, pt. 1, pp. 90*).—This contains the organization list, titles of the station bulletins issued during the year, a brief report of the director, departmental reports containing articles abstracted elsewhere, and a financial statement for the fiscal year ended June 30, 1906.

Annual Report of Porto Rico Station, 1906 (*Porto Rico Sta. Rpt. 1906, pp. 32*).—This report contains a summary of investigations conducted at the station during the year and separate reports by the horticulturist, entomologist and plant pathologist, and coffee expert. These are abstracted elsewhere in this issue.

Twenty-third Annual Report of Wisconsin Station, 1906 (*Wisconsin Sta. Rpt. 1906, pp. 321*).—This includes the organization list of the station, a report of the director on station work during the year, a list of bulletins issued by the station from 1883-1906, numerous articles abstracted elsewhere in this issue, the text of the State fertilizer and feeding-stuff laws with lists of the brands licensed, lists of exchanges and donations, and a financial statement for the fiscal year ended June 30, 1906.

Experiment Station Work, XL (*U. S. Dept. Agr., Farmers' Bul. 281, pp. 32, dgm. 1*).—This number contains articles on the following subjects: Insol-

ble phosphates; forms and methods of applying lime; sediment in irrigation water; hardy Bermuda grass; Williamson method of corn culture; killing sassafras sprouts; soluble oils for San José scale; corn as food for man; storing preserves and canned goods; incubation of chickens; prevention of nodule disease of lambs, and some milk terms.

List of publications of the agricultural experiment stations in the United States (*U. S. Dept. Agr., Office Expt. Stas. Bul. 180, pp. 10½*).—This gives the number, title, and author of each of the publications of the experiment stations from the time of their organization to June 30, 1906. The Office files of station publications from which this list has been prepared contain over 7,600 reports and bulletins.

Accessions to the Department Library, July-December, 1906 (*U. S. Dept. Agr., Library Buls. 61, pp. 61; 62, pp. 56*).

NOTES.

Alabama College and Station.—W. T. Clarke, entomologist, has resigned. The college announces the establishment of a 3-year degree course in veterinary medicine and surgery and of a chair of animal industry. D. T. Gray, formerly assistant in animal industry, has been appointed to the latter position and will divide his time between college and station work. A. J. Norman, a graduate of the Iowa College, has been appointed assistant in horticulture in the college and station, vice C. F. Kinman, who has resigned to accept a position with the Cuban Experiment Station. Plans are under way for the erection of a central dining hall and an infirmary.

Alabama Tuskegee Institute and Station.—P. C. Parks, farm superintendent, has resigned to assume charge of the agricultural department of Clark University at Atlanta, Ga.

Arizona Station.—E. E. Free, assistant chemist, has resigned and will be succeeded by W. H. Ross, of the University of Chicago. The vacancy in the horticultural department occasioned by the resignation of V. A. Clark, previously noted, has been filled by the appointment of J. E. Coit, of Cornell University.

California University and Station.—A dairy building, stock pavilion, and two cottages are being erected on the new farm at Davisville. Short courses will be opened there in the fall. Considerable experimental work is being planned.

Florida University and Station.—E. H. Sellards, professor of zoology and geology in the university and geologist in the station, has resigned to become State geologist.

Iowa College.—The cornerstone of the new four-story agricultural building was laid June 6 by Gov. A. B. Cummins, and the first story is now well under way. As planned, the building will have a frontage of 234 feet and a depth of 78 feet, besides an assembly-room wing with a frontage of 92 feet and a depth of 69 feet. Fireproof construction is to be used throughout, with granite base and Bedford stone walls, and the total cost with equipment will be about \$350,000. Arrangements have been made for the completion of the equipment on the poultry and dairy farm. The area of the college farm and grounds has been increased by recent purchases to a total of about 1,200 acres.

Maine University and Station.—Hon. S. W. Gould, of Skowhegan, has been appointed a member of the committee of the trustees on the experiment station, in the place of Hon. A. J. Durgin. L. H. Merrill, chemist to the station, has also been appointed professor of biological chemistry in the university. R. C. Gellerson, a recent graduate of the university, has been appointed inspector under the laws regulating the sale of feeding stuffs, seeds, fertilizers, foods, and drugs. W. M. Munson, for more than fifteen years horticulturist of the station, has resigned to accept a similar position at the West Virginia Station, where special emphasis will be given to plant breeding in its relation to pomology.

Massachusetts College and Station.—The Carnegie Foundation for the Advancement of Teaching has tendered a pension to Dr. C. A. Goessmann, and his retirement is announced. Doctor Goessmann has been professor of chem-

istry at the college practically since its establishment and chemist to the State board of agriculture since 1873. In 1882, upon the establishment of the State Experiment Station, he became its director and chemist, remaining in this capacity until its union with the Hatch Experiment Station. Since that time he has been chemist to the station, and a year ago was made honorary director. He will continue to act as consulting chemist to the station. C. Wellington, associate professor of chemistry, has been appointed professor of chemistry in the college.

The chemical work of the station has been united and amplified into a department of plant and animal chemistry, under the direction of J. B. Lindsey, of the division of foods and feeding, as chemist. E. B. Holland, as associate chemist, will have charge of a research division, H. D. Haskins of the fertilizer control work, and P. H. Smith of the feed and dairy division. R. D. MacLaurin, Ph. D., at present of the Rockefeller Institute, has been engaged as a chemist in the research division. G. H. Chapman, a recent graduate of the college, has been appointed assistant in the department of botany and plant pathology in the station, vice N. F. Monahan, resigned. P. A. Russell, of Great Barrington, has been appointed to the board of trustees.

In the college the department of horticulture has been reorganized as a division of horticulture, to include at present departments of pomology, landscape gardening, and floriculture. F. A. Waugh is the head of the new division, with the title of professor of general horticulture and professor of landscape gardening, and E. A. White will continue in charge of the work in floriculture. F. C. Sears, professor of horticulture in Nova Scotia Agricultural College, has been appointed to the professorship of pomology, and F. M. Gracey, a graduate of the Massachusetts Normal Art School, has been made assistant in landscape gardening. S. B. Haskell, instructor in agriculture, has been granted a year's leave of absence for graduate work at the University of Leipsic.

Minnesota University and Station.—W. M. Liggett has resigned as dean and director on account of failing health, and has been appointed superintendent of the Grand Rapids Substation. He is succeeded by E. W. Randall, of the board of regents.

Missouri University.—John M. Eppard, a graduate of the University of Illinois, has been appointed assistant to the dean.

New Jersey Stations.—The resignation is noted of Miss J. A. Voorhees, assistant horticulturist.

New York State Station.—Appointments have been made as follows: J. G. Grossenbacher as assistant botanist, M. J. Dorsey as assistant horticulturist, and Otto McCreary and J. T. Cusick as assistant chemists.

North Carolina Stations.—The experimental work of the State board of agriculture has been organized as an experiment station, to be known as the Agricultural Experiment Station of the North Carolina State Department of Agriculture, and with the following staff: B. W. Kilgore, director, farm crops; Tait Butler, veterinarian, animal husbandry; W. N. Hutt, horticulturist; Franklin Sherman, jr., entomologist; T. B. Parker, cooperative experiments; W. M. Allen, chemist, foods; C. D. Harris, assistant chemist and microscopist, stock feeds; Miss H. M. Card, assistant chemist, foods; J. M. Piekel, W. G. Haywood, L. L. Brinkley, and S. O. Perkins, assistant chemists; G. M. MacNider, soils; L. M. Smith, assistant entomologist, and R. W. Scott, F. T. Meacham, J. H. Jefferies, and R. W. Collett, superintendents of the substations at Edgecombe, Iredell, Pender, and Transylvania, respectively. Of these, Messrs. Kilgore, Butler, Hutt, and Sherman have resigned corresponding positions in the college station, which, as previously announced, is to be maintained

under separate management. C. B. Williams, now agronomist, has been appointed director of the latter.

Ohio University and Station.—J. W. Decker, professor of dairying in the university, died June 21 of pleuro-pneumonia at his country home near Columbus. Miss Minnie A. Stoner, head of the department of domestic science, has resigned to accept the position of dean of women and professor of domestic science in Wyoming University. A cattle building, a stock judging pavilion, and a horse building are under construction at the university and will be completed this fall at a total cost of \$80,000. T. E. Manns has been appointed assistant plant pathologist in the station, vice J. M. Van Hook, who has resigned to accept a position with the University of Indiana.

Virginia College and Station.—M. P. Jarnagin, J. R. Fain, and P. O. Vanatter have resigned to accept the professorships of animal husbandry and experimental agronomy and the superintendency of field demonstrations, respectively, in the Georgia College, to take effect September 1.

Washington College and Station.—The presidency of the college and directorship of the station have been separated, and R. W. Thatcher, chemist of the station, has been appointed director, to take effect September 15.

West Virginia University and Station.—John L. Sheldon has been appointed professor of bacteriology and plant pathology in the medical department of the university and is no longer connected with the station.

Wisconsin University and Station.—Mazzyck P. Ravenell, Ph. D., late assistant medical director of the Henry Phipps Institute for Tuberculosis, Philadelphia, has been elected head of the department of bacteriology in the university and station. J. L. Sammis, Ph. D., who has been connected with this Department in its cooperative cheese investigations with the station, has been elected assistant professor of dairying. E. V. McCollum, Ph. D., of Yale University, and Shin-kichi K. Suzuki, a graduate of Sapporo Agricultural College, have been elected, respectively, instructor and research assistant in agricultural chemistry, and A. J. Rogers, jr., and Charles Knight, recent graduates of the college of agriculture, assistants in horticulture and in fertilizer and feeding-stuffs inspection, respectively.

Wyoming University and Station.—B. C. Buffum, professor of agriculture and horticulture in the university and director of the station, has resigned to engage in commercial work. J. D. Towar, formerly of the Michigan College and Station, and more recently principal of the Roseworthy Agricultural College in South Australia, has been appointed director and entered upon his duties July 1. J. A. Hill, a recent graduate in the agricultural course, has been appointed wool expert in the station and placed in charge of its wool investigations under the Adams fund. R. E. Hyslop, instructor in horticulture in the university and agronomist in the station, has resigned.

Association of Official Agricultural Chemists.—The twenty-fourth annual convention will be held October 9-12 at Norfolk, Va., under the auspices of the Jamestown Exposition.

International Congress of Agriculture.—The Eighth International Congress of Agriculture was held at Vienna May 21-26, with over 2,000 delegates and visitors in attendance. The congress was opened by Prince Carl Auersperg. Senator and Ex-Minister of Agriculture Jules Méline, of France, delivered the opening address on The Return to Mother Earth, in which he made a strong plea for agriculture and rural life, in both its economic and social phases. In his opinion a very marked tendency is now manifested in most countries to give to the tillers of the soil a higher social position. An indication of this was evidenced in the placing of the palatial parliament building at the disposal of

the congress for its meetings, a privilege never before accorded to representatives of agriculture. For the transaction of business the congress was organized into eleven sections, among which were those on rural economics, agricultural education, farm machinery, crops and plant industry, brewing, and irrigation and drainage.

Papers on the organization and function of the experiment stations were submitted by Dr. F. W. Dafert, of Vienna, Dr. Thomas Kosutány, director of the Hungarian experiment station at Budapest, and Dr. A. C. True, of this Office. In these papers the chief function of the stations was declared to be investigation in agriculture, and the necessity of relieving the chief officers of essentially all work of instruction and of control work involved in the execution of the laws relating to agriculture was emphasized. Resolutions embodying these conclusions were adopted by the section.

As in previous years, special attention was given by the congress to a discussion of farm mechanics. The desirability and importance of establishing international rules for the testing of farm machines were pointed out, although it was admitted that in the testing of tools used for the cultivation of the soil, the soil conditions made the establishment of definite conditions for such tests practically impossible. Attention was called to the importance of instruction in the use of farm machines in agricultural schools, including practical work in the construction and repair of implements and actual field tests.

During the congress trips were made to the local experiment station, the agricultural high school, and other points of interest. The utmost hospitality was shown by the citizens and officials of Vienna, receptions being tendered by the mayor, Emperor Francis Joseph, and others.

Korean Experiment Station.—An agricultural and model station was recently established by the Japanese government, at an expense of \$85,000, at Suwon, Korea. The station was formally opened on May 15, and turned over to the Korean government. Under the direction of Japanese experts the following lines of work are to be undertaken: The increase of the productivity of the land throughout the country by securing a better geographical distribution of the different kinds of produce according to climate and soil, the improvement of the quality of agricultural seeds, the introduction and acclimatization of new varieties of farm products, the supplying of farmers with good manures, irrigation, drainage, and protection against inundations, the utilization of waste lands, the improvement of poultry and dairy farming, sericulture, and the growing of by-products on the farm.

New Forestry School.—A school of forestry, offering a four-year course leading to the degree of bachelor of science in forestry, will be established at the University of Washington at the beginning of the next college year. Instruction in this subject has been given at the university since 1895. The university campus comprises 355 acres of land adapted under the climatic conditions of Puget Sound to the growing of a wide variety of forest trees. The university also owns large tracts of land in various sections of the State, on which extensive experiments may be conducted.

New Botanical Journal.—The International Association of Botanists has established a new journal, *Progressus rei Botanicae*, under the editorship of its secretary, Dr. J. P. Lott, of Leiden. Its initial number consists of articles on The Ontogeny of the Cell since 1875, by E. Strasburger; The Present Position of Paleozoic Botany, by Dr. H. D. Scott; Bibliography of Literature on Paleozoic Fossil Plants, by E. A. Newell Arber; and The Progress of Botanical Geography since 1884, by C. Flahault.

Necrology.—The *Journal d'Agriculture Pratique* announces the death of Louis Gustave Heuzé, in Paris on April 18, in his ninety-first year. Heuzé, as professor of agriculture, had been connected at different times with various institutions in France, and for more than fifty years had been one of the editors of the *Journal d'Agriculture Pratique*. He was a voluminous writer, particularly on agricultural topics. Among his best-known works are *Les Plantes Céréales*, *Les Plantes Fourragères*, *Les Pâturages*, *Les Prairies Naturelles et les Hersages*, *Les Plantes Industrielles*, and *Les Plantes Légumières Cultivées en Plein Champ*, many of which have been issued in numerous editions.

Sir Dietrich Brandis, the "father of systematic forest management in the British Empire," died at Bonn, March 28, in his eighty-third year. His work was done largely in India, where he developed the present extensive forest system and organized at Dehra the first forestry school, now the Imperial Indian Forest School. Through the training of a large number of forestry experts, he also had a great share in the development of forest conservation in this country. His chief publication is *Indian Trees*, which appeared in 1906.

Dr. Alexander Buchan, the eminent Scotch meteorologist and secretary of the Scottish Meteorological Society since 1860, died May 13, at the age of 78. Among his publications were the *Handy Book of Meteorology*, in 1867, an *Introductory Text-Book of Meteorology*, in 1871, and many maps and charts.

The death is noted of Sir Benjamin Baker, the distinguished English engineer, whose name is associated with many great irrigation works of Egypt.

Alfred Newton, ornithologist and professor of zoology and comparative anatomy in the University of Cambridge for many years, died June 7.

Dr. Maxwell T. Masters, for many years editor of *The Gardeners' Chronicle*, died May 30, at the age of 74. He was a prolific writer on horticultural and forest botany, and his work on *Vegetable Teratology*, first published in 1869, remains a standard work.

Miscellaneous.—According to *Breeders' Gazette*, A. E. Parr, Ph. D. (Leipsic), a graduate of the University of Edinburgh, and who recently received the degree of M. S. A. from Iowa State College for work in animal husbandry, has been appointed director of agriculture and animal husbandry of British India and will have charge of the 39 experiment stations of that country. It is stated that the salary attached to the position is \$10,000 a year for ten years, followed by a pension of \$5,000 a year for life.

At the recent session of the Texas legislature a law was passed requiring the teaching of agriculture in the public schools of the State.

According to *Science*, Dr. John Brittain, professor of chemistry at New Brunswick University, has been appointed to the chair of nature study at the MacDonald Agricultural College.

T. B. Wood has been appointed Drapers' professor of agriculture in the University of Cambridge, to succeed T. H. Middleton, whose resignation has been previously noted.

Dr. A. W. Harris, formerly director of this Office, was installed as president of Northwestern University, June 20.

Dr. Otto Folin, research chemist at the McLean Hospital for the Insane, has been appointed associate professor of biological chemistry at the Harvard Medical School.

EXPERIMENT STATION RECORD.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of the Record is \$1 per volume, or 10 cents per number. The prices of other technical publications are given in the list above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XVIII.

AUGUST, 1907.

No. 12.

Dr. Charles A. Goessmann, of Massachusetts, who retired from active service with the close of the college year, has long been one of the most conspicuous figures in agricultural chemistry in this country. For nearly forty years he has been an active member of the faculty of the Massachusetts Agricultural College, his service covering almost the entire period since the college was established. One of the earliest pioneers in agricultural investigation, his work has been not only a contribution to knowledge, but an inspiration to others and a potent influence for the development of agricultural experimentation. It has exhibited unusual versatility and breadth of knowledge, and has been characterized by a thoroughness and conservatism which have given great reliability to his conclusions. The celebration of his eightieth birthday just before commencement and his retirement as emeritus professor and under a pension from the Carnegie Institution close an active career full of honor to himself and of service to his fellow-men.

Doctor Goessmann was educated at the University of Göttingen, Germany, receiving his doctorate in 1853. While there he became the favorite student and later the assistant of the eminent chemist Wöhler, from whom he received his inspiration to follow chemistry rather than pharmacy, which had been his original choice. His investigations in the Göttingen laboratory were of a fundamental character and covered a wide range of organic compounds. The results were embodied in something over twenty papers published in *Annalen der Chemie und Pharmacie*. Many of these related to the constituents of plant and animal products, such as peanut oil, in which he discovered two new fatty acids, cocoa oil, strychnin, leucin (a product of pancreatic digestion of proteids), hippuric acid, and others; and as early as 1857 he reported upon "a new sugar plant, *Sorghum saccharatum*."

In that year he accepted from a former American fellow-student the position of scientific director of an extensive sugar refinery in Philadelphia. Following this he studied the sugar industry in Cuba and the West Indies and in 1861 became chemist of the Onondaga

Salt Works, at Syracuse, N. Y. There he remained until 1869, making in the meantime important contributions upon the chemistry of brines and reporting upon the salt deposits in Canada and Louisiana. A portion of each year was spent at Rensselaer Polytechnic Institute as professor of physics and chemistry. He resigned from this position early in 1869 to accept the professorship of chemistry in the Massachusetts Agricultural College, at the instance of his old friend and classmate at Göttingen, President W. S. Clark of the college.

His familiarity with the methods of agricultural instruction in Germany and his high educational standards made him an influential factor in shaping the courses of the young institution. Industrious and resourceful to a degree, he made the most of inadequate accommodations and equipment and introduced the laboratory method of instruction in his department. This, together with the attention which he gave to the practical applications of chemistry in agriculture and the industries, served to make his courses both instructive and practical. His students soon came into demand for industrial positions, and his laboratories were for many years a training ground for agricultural and technical chemists, who have been called to important positions in every part of the country. As a teacher, it was his advanced students especially who came to know him as a scholar, and who received from him inspiration and encouragement for further study, which has led an unusual number of them to go abroad for that purpose.

Almost immediately after going to the college Doctor Goessmann took hold of the agricultural problems of the State, both practical and scientific, and made them the subject of investigation. At that time agricultural investigation had made but little headway in this country. He was a pioneer in every sense of the word, and he brought to his studies a broad training in science, full confidence in its ability to reveal the laws upon which agriculture depends, and the true scientific spirit which seeks only the truth. In 1873 he was appointed chemist to the State board of agriculture, and then began a series of reports and lectures which has continued almost to the present time. He investigated the fertilizer industry of the State, at that time in a most unsatisfactory condition, outlined changes in the existing law, and established an efficient system of official control, the first of its kind in any State.

He early introduced the valuation system, which enabled farmers to intelligently interpret the results of analysis, established confidence in the value of agricultural analysis, and dispelled the illusions of the day as to special mysterious qualities of fertilizer mixtures not represented by their analysis. His reports were replete with information upon the condition of the fertilizer trade, the sources of fertilizing materials, the manurial requirements of crops, the use of

refuse and local supplies, the home mixing of fertilizers, and similar matters, which made them especially valuable at that stage. His conscientious work in this line gave him a prominent position among the fertilizer inspectors of the country, and when the latter organized the Association of Official Agricultural Chemists, in 1880, he was elected its first president.

Doctor Goessmann's studies in agricultural chemistry prior to the establishment of the experiment station covered a wide range of subjects and attracted much attention the country over. They served to confirm the popular expectation that the agricultural college would render aid to the farmer and to agriculture in general, as well as furnish an education to his sons. To him more than to any other man was due the reputation of the college as an institution for investigation in agriculture, and such was the high character of his work that it received the commendation of men of science and caused many honors to fall upon him. His previous interest in sugar production led him to make extensive experiments in the manufacture of sugar from sorghum and later from the sugar beet. His conclusions as to the practical value of sorghum as a source of sugar, although not accepted at the time, have been fully borne out by subsequent experience. His work upon the sugar beet was epoch-making and was a practical demonstration of the feasibility of beet-sugar production in the United States. It was the starting point of the more recent studies and propaganda in that line.

Doctor Goessmann early began the advocacy of an experiment station at the college, illustrating by his studies the practical value of such an institution to the agriculture of the State. A station was established in 1878 with private contributions, and while studies were prosecuted with the proceeds of the fertilizer inspection it was not until 1883 that the State made definite provision for a station. He was then appointed director and remained at its head until it was merged with the Hatch Station of the college, in 1895. Since that time he has been chemist and has had charge of the fertilizer inspection. Under his direction the station became an efficient aid to the farmer and to the agriculture of the State, and was from the first one of the leading institutions of its kind in the country.

The occasion of Doctor Goessmann's retirement was made one of honor to the man who has served the college, the State, and the cause of agriculture so long and effectively, and for expression of the affectionate regard in which he is held by his former students. At special exercises following the alumni banquet at commencement, addresses of appreciation and of congratulation were made, and he was presented with a handsome stained-glass tablet, appropriately inscribed and decorated, as a tribute from the alumni of the college. His has been a notable career, and has witnessed vast changes in the

attitude toward agricultural education and experimentation, and in the condition of agricultural science. To few men has it been given to contribute a greater or more important part in this development, and in the evening of life he may well contemplate these changes with a sense of gratification at the progress made and of satisfaction at the part he has played.

The distinguished French scientist, Jean Dumas, declared more than half a century ago that one of the most important lessons for the farmer to learn is how to produce good barnyard manure and to use it rationally; that the fundamental agricultural question is and will remain the manure question. Investigations since Dumas's time have but tended to confirm his views, recent investigators on the subject especially serving to bring the matter into prominence and to throw a new light upon the function and efficiency of such manure in the soil. It has long been understood, of course, that the fertilizing value of manure was not determined entirely nor possibly mainly by its content of nitrogen, phosphoric acid, and potash, but by its physical action and other indirect effects not very clearly defined or understood.

Modern investigation, which has placed constantly increasing emphasis on biological processes in relation to soil fertility, is making it quite clear that manure is one of the most powerful agents commonly available on the farm for promoting or controlling these processes.

The soil bacteriological studies which have so rapidly multiplied in recent years have shown that manure and similar organic materials, when properly prepared, not only furnish a readily available supply of the carbonaceous food required for the active growth of soil organisms, but may be made to furnish an easy practical means of inoculating the soil with beneficial organisms, thus indirectly increasing their productiveness.

These bacteriological studies are beginning to show how the injurious effects (denitrification, etc.), which have been ascribed to the use of manure may be obviated by proper preparation and use of this material. For example, Julius Stoklasa, director of the chemical-physiological experiment station of Prague, has recently worked out a very conclusive bacteriological explanation of the advantage of the practice, which is now generally recommended by the best authorities on the subject, of applying small quantities of manure at frequent intervals instead of making large applications at longer intervals. He shows that the frequent small applications keep the soil supplied with a sufficient and constant supply of the carbonaceous food required by the beneficial organisms, without bringing about the condi-

tions favoring the predominance of injurious organisms which would result from larger applications at any one time.

It has thus been shown to be possible by the proper handling of manure to promote the activity of the micro-organisms which (1) fix atmospheric nitrogen, (2) transform nitrogenous organic matter into more available compounds, and (3) act directly by the carbon dioxide they produce on the insoluble phosphates and potash compounds of the soil to render them available for the use of the higher plants, without at the same time incurring any serious risk of loss by denitrification or other injurious processes.

When we reflect that the above statements indicate only a few of the many ways revealed by recent investigations in which soil fertility is affected by bacteriological processes, we can readily believe that further research in this most promising field will render necessary a radical revision of many of the commonly accepted notions of soil fertility and help to put many features of present methods of fertilizing and soil management on a more rational basis.

Recent discoveries in soil bacteriology give a peculiar significance to Berthelot's dictum that the soil is a living thing (*la terre est quelque chose de vivant*) and furnish one of the many evidences of the keen insight of that eminent scientist. It was this keen scientific discernment, says Lipman, "that largely contributed to a better appreciation of soil bacteriological activities as a factor in plant production. His experiments dealing in the main with specific bacteriological processes, just as the work of Schloesing and Müntz, Warington, and Winogradski, of Dehérain and Maquenne, of Gayon and Dupetit, or of Hellriegel and Wilfarth dealt with specific processes, furnished none the less a strong argument for a more systematic study of soil bacteria in general, and led gradually to the recognition of bacteriological methods as a valuable aid in the study of soil problems. Henceforth the soil chemist, soil physicist, and soil bacteriologist, working in harmony, must each do his share in the solution of these problems."

Development in the field of soil bacteriological investigations has not been as rapid, nor has the subject received as wide attention, in this country as abroad. This is true despite the widespread activity in soil studies and fertilizing problems. This Department and a few of the experiment stations have made important contributions to this subject, particularly in the field of fixation of nitrogen by micro-organisms in symbiosis with leguminous plants. The study of soil bacteriology in its broader aspects, however, has been limited to the work of a comparatively small number of investigators in this country. These phases include the fixation of nitrogen, both symbiotic and nonsymbiotic, nitrification and other biological processes

of transforming nitrogen compounds in the soil, the rôle of micro-organisms in rendering available the mineral constituents of plant food in the soil, and a number of other processes having an intimate bearing upon soil fertility and productiveness.

"Soil bacteriological research," says Lipman, "offers splendid opportunities for the collection of facts of utmost moment, not alone to the theory of agricultural science, but also to its practice. It is safe to assert that systematic investigation in this field will reward us richly in a broader knowledge of plant-food production and plant-food assimilation. It will enable us to gauge with far greater certainty the various phases of soil fertility and to make better provision for the economic utilization of the plant food derived from soil sources or from the manures and fertilizers applied."

Realizing the importance of this subject and the widely scattered condition of the literature relating to it, the Office has in course of preparation for early publication a review of investigations in soil bacteriology, prepared by Doctor Lipman of the New Jersey Station. It is hoped that this summary will serve to call attention to the progress already made, to indicate the possibilities of the subject, and to stimulate further and broader inquiry in that field in this country.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

A revision of the atomic weight of potassium, T. W. RICHARDS, A. STAEBLER, and E. MUELLER (*Jour. Amer. Chem. Soc.*, 29 (1907), No. 5, pp. 623-656).—Determinations based upon the analysis of potassium chlorid and bromid are reported. These agree in showing that the atomic weight of potassium is 39.114.

A new method of determining the alkalinity of ashes, K. FARNSTEINER (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 13 (1907), pp. 305-338; *abs. in Analyst*, 32 (1907), No. 374, p. 181).—In the method proposed the ash is dissolved in a known volume of standard acid, phosphates are precipitated by the addition of calcium chlorid and a known quantity of ammonia, and the excess of ammonia is then titrated back. The results obtained by this method are usually much lower than those yielded by direct titration.

Methods of examining milk and milk products, C. BARTHEL (*Die Methoden zur Untersuchung von Milch und Molkereiprodukten*. Leipzig: M. Heinsius, 1907, pp. VII+271, figs. 59; *abs. in Rev. Gén. Lait*, 6 (1907), No. 8, pp. 185-187).—This is a complete treatise on the analysis of milk and its products. The chapters deal successively with the examination of milk, butter, cheese, milk products, and the decomposition products of milk, butter, and cheese.

On the methods of determining fat in milk, M. BEAU (*Lait, et Indus. Ferme [Paris]*, 17 (1907), No. 8, pp. 57-60).—The relative values of the practical and more technical laboratory methods of determining fat in milk are discussed. Preference is expressed for the Röse-Gottlieb method.

Tests of the salt method, K. JAROSS (*Milchw. Zentbl.*, 3 (1907), No. 5, pp. 185-199).—The Gerber salt or alkali method for determining milk fat was compared with the Gerber acid method and also with the Gottlieb method and the data so obtained are used as a basis for a discussion of the various advantages and disadvantages of the salt method.

Notes on the determination of total solids in milk and on formulas used in milk control, P. GOBERT and M. BOUIN (*Rev. Gén. Lait*, 6 (1907), Nos. 9, pp. 193-200; 10, pp. 224-230).—The various methods of determining or of calculating by means of formulas the solids in milk are discussed, emphasis being laid upon the importance for purposes of milk inspection of determining the fat free extract or the ratio of fat to total solids.

The detection of cocoanut oil in butter, E. HINKS (*Analyst*, 32 (1907), No. 374, pp. 160-162).—The method described depends upon the formation of needle-shaped crystals by cocoanut oil. It is as follows: The melted and filtered fat is dissolved in ether and the solution cooled. The solid glycerids separate out in about one-half hour, leaving a clear ethereal solution which is filtered and

evaporated. The residual fat is dissolved in boiling alcohol. After cooling for 15 minutes at 5° C. the alcoholic layer is filtered and cooled to 0° C., when the characteristic crystals are deposited and identified by a magnification of 250 to 300 times.

Detection of cocoanut oil in butter, W. LUDWIG and H. HAUPT (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 13 (1907), No. 10, pp. 605-610).—Studies of the refraction and color reactions of the different fatty acids in butter and cocoanut oil are reported. The addition of cocoanut oil to butter, according to the results obtained, lowers the index of refraction and favors the formation of a red color with anilin and furfurool.

On the practical importance of the reducing power of milk, E. BRAND (*München. Med. Wchnschr.*, 54 (1907), No. 17, pp. 821-823).—Schardinger's reaction is considered an important means of judging the quality of milk. The method, as given by the author, is as follows: To 10 cc. of milk at a temperature of 68 to 70° C. is added 0.5 cc. of a reagent composed of formalin 5 cc., saturated alcoholic solution of methylene blue 5 cc., and water 190 cc. The methylene blue should be entirely reduced within 6 minutes. A second sample boiled for a short period and then treated with this reagent should not be decolorized.

The fractional distillation of coal-tar creosote, A. L. DEAN and E. BATEMAN (*U. S. Dept. Agr., Forcst Serv. Circ.* 80, pp. 31, figs. 17).—This circular gives preliminary results of a study of the influence of the vessel on the fractional distillation of creosote, the influence of the rate of creosote distillations, the temperatures for taking fractions, and the sources of error in creosote fractionation.

Report of the division of chemistry, B. L. HARTWELL, M. STEEL, and J. P. GRAY (*Rhode Island Sta. Rpt.* 1906, pp. 181-185).—A brief account of the work of this department of the station during 1906 is given, with analyses of miscellaneous materials, including ground limestone, hydrated lime, limekiln ashes, guano, basic slag, acid phosphate, muriate of potash, sulphate of potash, potassium carbonate, nitrate of soda, sulphate of ammonia, dried blood, acidulated fish, tankage, bone, corn meal, and mixed feed.

Annual reports on the progress of chemistry for 1906 (*London: Guerney & Jackson, 1907, pp. IX+387*).—This is the third volume of this series of reviews of progress in chemistry issued by the London Chemical Society. As heretofore, it includes reports on general and physical chemistry by A. Findlay, inorganic chemistry by P. P. Bedson, organic chemistry by H. J. H. Fenton, J. B. Cohen, and J. T. Hewitt, stereochemistry by W. J. Pope, analytical chemistry by A. C. Chapman, physiological chemistry by W. D. Halliburton, agricultural chemistry and vegetable physiology by J. A. Voelcker, mineralogical chemistry by A. Hutchinson, and radioactivity by F. Soddy.

The section on agricultural chemistry and vegetable physiology (pp. 256-293) reviews progress during 1906 in investigations relating to fixation of the nitrogen of the air in the form of calcium nitrate and calcium cyanamid, and the agricultural utilization of these products; the fixation of nitrogen by micro-organisms in the soil; the assimilation of nitrogen by plants directly and through their root tubercles; nitrification, denitrification, and decomposition of nitrogenous matter in the soil; nitrogen in rain water; green manuring and humus of the soil; optimum ratio of lime to magnesia in soils; conditions influencing the availability of phosphates in soils; the assimilation of potash and soda by plants; the utilization of the rarer constituents (manganese, copper, aluminum, mercury, silver, iodine, and fluorine) by plants; methods of studying the availability of soil constituents; the influence of sterilization and oxidation upon the availability of soil constituents; and germination, assimilation, development, micro-

organisms, enzymes, glucosids, cyanogenesis, foods and feeding, crops, strength in wheat, quality in barley, sugar, tea, tobacco, cinchona, cassava, eggs, and milk.

It is stated that the most notable progress made during the year was in investigations relating to the utilization of the nitrogen of the air by artificial means and by micro-organisms, although considerable progress was made in investigations relating to green manuring, strength in wheat, and the sugar industry. In the reviewer's opinion, the utilization of the nitrogen of the air by artificial means now resolves itself simply into a question of cost, and on this point nothing is at present definitely known.

The numerous experiments which have been made indicate quite clearly that the calcium nitrate, or lime niter, is in general as efficient as sodium nitrate as a fertilizer, and sometimes produces better results, particularly on soil needing lime. Calcium cyanamid, or lime nitrogen, has been found under favorable conditions and on soils not rich in humus or deficient in lime to be nearly as efficient as ammonium sulphate or sodium nitrate for most crops. It seems, however, not to be well suited for top-dressing or mixing with other fertilizing materials and undergoes deterioration in storage.

The reports of investigations on which the review is based have been noted from time to time.

METEOROLOGY—WATER.

Monthly Weather Review (*Mo. Weather Rev.*, 35 (1907), Nos. 1, pp. 1-50, figs. 3, charts 10; 2, pp. 51-102, figs. 5, charts 9).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of January and February, 1907, monthly review of the progress of climatology throughout the world, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 1.—The Kingston Earthquake, by C. F. Marvin; The Geodetic Institute at Potsdam; Permanence of Climatic Conditions; The Adirondack Rainfall Summit (illus.), by R. E. Horton; The Climate of Kansas (see below); Waterspouts in Maryland, by W. L. Mayo; Weather Bureau Men as Educators; The Climate of Yukon Territory, by R. F. Stupart; Problems in Meteorology, by C. F. von Herrmann; Problems in Mixtures of Air and Vapor; and The Growth of Fog in Unsaturated Air (illus.), by F. W. Proctor.

No. 2.—Notes of a Meteorologist in Europe, by H. J. Cox; A Beneficent Scientific Mission: Interconversion of Centigrade and Fahrenheit Degrees; Meteorological Work at Camp Wellman, Danes Island, Spitzbergen; A Climatic Sketch of Tacoma, Wash., by E. B. Gittings, jr.; Snow Rollers at Canton, N. Y. (illus.), by M. L. Fuller; E. Scharf on the Effects of Hail on Crops; Long-range Indian Monsoon Forecasts; Long-range Seasonal Forecasts for South Africa; Wilhelm von Bezold; A Winter Waterspout (illus.), by D. Cuthbertson; International Meteorology; Rainfall and Outflow Above Bohio, in the Valley of the Chagres, by H. L. Abbot; Panama Rainfall, by E. B. Garriott; Observation of Cloud Altitudes at Nighttime; and Fog on the Newfoundland Banks, by C. T. Brodrick.

The climate of Kansas (*Mo. Weather Rev.*, 35 (1907), No. 1, pp. 13, 14).—This article gives a verbatim copy of the stenographic report of the testimony of the Chief of the Weather Bureau before the Committee on Agriculture of the House of Representatives January 8, 1907, bearing on the subject of climate of Kansas, as well as a statement summarizing observations on rainfall at different points in Kansas and contiguous territory during the last 30 years.

The data are classified in 10-year periods. The averages show that the first and last 10 years were periods of fairly abundant rainfall and that the middle

10 years was a period of deficient rainfall in this region. "There is practically no difference between the rainfall of the first 10 years and the last 10 years. . . . An examination of the wind records in Kansas and Nebraska shows that the last 15 years have not been quite so windy as the 15 years previous, and this is especially true of the years 1904, 1905, and 1906. It is not safe to assume, however, that a permanent decrease in the wind velocity has taken place."

Meteorological observations (*Maine Sta. Bul. 137, pp. 299-301*).—Observations at Orono on pressure, temperature, precipitation, cloudiness, and wind movement are summarized for each month of the year. The mean yearly pressure was 29.88 in., the temperature 43.5° as compared with 42.23° for 38 years. The precipitation was 39.11 in. as compared with 43.84 in. for 38 years, and the number of cloudy days was 154. Monthly and annual summaries of precipitation at 23 places are also given.

Report of meteorologist, N. HELME (*Rhode Island Sta. Rpt. 1906, pp. 317-333*).—Observations at Kingston on temperature, precipitation, prevailing winds, and general character of the weather are given for each month of the year ended June 30, 1906. The mean temperature for that period was 48.4°, the precipitation 53.57 in., and the number of clear days 175.

The underflow of the South Platte Valley, C. S. SLICHTER and H. C. WOLFF (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 184, pp. 42, figs. 13*).—Investigations carried on mainly at Ogalalla, Nebr., but also to some extent at North Platte, "to determine what resources, if any, existed in the underflow waters of the valley and whether it was practicable to make use of such waters, if they were found to exist in suitable quantities, for purposes of irrigation," are reported.

The results indicate that there is an ample supply of ground water at an average depth of 40 to 60 ft., in the South Platte Valley, for a large number of small pumping plants located in almost any part of the bottom lands. Suggestions for the construction of such small pumping plants are given.

Water resources of the Rio Grande Valley in New Mexico and their development, W. T. LEE (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 188, pp. 59, pls. 10, figs. 2*).—Observations during the field seasons of 1904 and 1905 over an area extending along the Rio Grande from the southern boundary of New Mexico northward to Santa Fe are reported. The data reported deal with geography, geology, water supply, reservoir sites, and utilization of the water supply.

The general conclusion is reached that while the flood plain material of the low lands along the river is saturated, it does not in general allow the water to pass through freely enough for the successful use of shallow irrigation wells. Deep wells may, however, be more successfully employed. The conditions in many places are apparently favorable for the establishment of reservoirs to store the large amount of flood water which passes down the Rio Grande at certain seasons.

Stream pollution by acid-iron wastes, H. STABLER (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 186, pp. 36, pl. 1*).—The investigations at Shelby, Ohio, reported in this bulletin included "(1) the history of the pollution and the attendant litigation, (2) the effect of acid-iron liquors upon sewage purification processes, (3) the conditions along the stream, and (4) the disposal of acid-iron wastes without discharge into water-course or sewerage system." Lost acid used in pickling is the present cause of pollution, and it is suggested that "by designing the plant so that this waste may be recovered as copperas, stream pollution can be practically obviated and the economic value of the plant greatly enhanced."

Investigations on the purification of Boston sewage, C. E. A. WINSLOW and E. B. PHELPS (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 185, pp. 163, figs. 22*).—This paper contains a history of the sewage disposal problem and reports the results of experiments made at the Sanitary Research Laboratory and Sewage Experiment Station of the Massachusetts Institute of Technology.

It is stated that actual practice in Europe, outside of England, is still largely confined to chemical treatment and irrigation. In England the tendency has been largely toward the use of rapid processes of treatment.

In the United States sewage disposal practice differs widely in different localities. In New England intermittent filtration through sand has been largely used and found very satisfactory. West of the Appalachian Mountains the newer biological processes are being rapidly introduced. In the extreme West the use of sewage for irrigation is often favored.

In the experiments in the treatment of Boston sewage very satisfactory results were obtained by the process of purification by trickling over beds of coarse material. It was found in these experiments that the sewage could be "successfully filtered through a 2-ft. bed of sand with an effective size of 0.14 mm., at a rate of 0.4 million gallons per acre per day, divided into 4 doses in the 24 hours. Such high rates should not be expected in actual practice, but it is believed that with care in construction and operation the sand filter may be efficient at higher rates than have been generally advocated. . . . Crude Boston sewage may be treated in single-contact beds of fine stone (one-half inch in diameter) at a rate of about 1.2 million gallons per acre per day." A bibliography of 110 references is given.

SOILS—FERTILIZERS.

The value of poultry manure, E. and W. BROWN (*Jour. Bk. Agr. [London], 13 (1907), No. 12, pp. 719-727*).—Observations made at the poultry farm of University College, Reading, on the amount of manure produced by different kinds of fowls under different systems of feeding, on the composition and relative value of the manures, and on methods of caring for and using poultry manure are reported.

The results of observations on the production of manure were as follows:

Production of manure by different kinds of fowls.

Kind of fowl	Weight of fowl.	Age of fowl.	Feed.	Weight per week of manure (collected and weighed daily).
	<i>Lbs. oz.</i>			<i>Lb. oz.</i>
Wyandotte cock.....	6 12	16 months..	Ration of barley, wheat, and bran, with green food.	1 13
Faverolles hen.....	5 12	15 months..do.....	1 11½
Growing chicken.....	3 12	14 weeks....do.....	1 2½
Fattening bird.....	3 8	15 weeks....	Crammed with ground oats and skim milk.	1 13½

Similar but less complete observations were made with ducks, geese, and turkeys. A 7-lb. duck produced 6 lbs. and 10¾ oz. of manure per week, a 17-lb. turkey 4 lbs. and 1½ oz., and a goose 10 lbs. and 1 oz.

The following table gives analyses of the manure of fowls under the ordinary conditions of a poultry farm:

Composition of poultry manure.

Name of fowl.	Moisture.		Nitrogen.		Phosphoric acid.		Potash.	
	Fresh sample.	Air-dried sample.	Fresh sample.	Air-dried sample.	Fresh sample.	Air-dried sample.	Fresh sample.	Air-dried sample.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Birds at liberty	59.50	9.96	1.75	3.99	1.00	2.27	0.54	1.22
Birds in confinement	68.30	9.50	1.47	4.21	.71	2.04	.49	1.40
Fattening birds	70.30	15.00	2.28	6.52	.97	2.77	.55	1.57
Ducks at liberty	78.00	10.00	1.20	4.90	1.09	4.46	.39	1.60
Geese at liberty	82.60	9.10	.53	2.80	.19	.97	.34	1.80
Turkeys at liberty	71.70	8.00	1.02	3.70	.66	2.40	.47	1.70
Chickens one month old	72.80	11.00	1.71	5.56	.48	1.56	.43	1.10
Chickens three months old	77.70	11.10	.90	3.61	.35	1.44	.28	1.14

The value and use of poultry manure are discussed as follows: "Fowl excreta form a distinctly nitrogenous manure which stimulates vigorous growth of the leaves, stems, and roots of plants generally as much as a dressing of nitrate of soda or sulphate of ammonia. It contains, however, in addition to nitrogen, an appreciable amount of phosphates and potash in a rapidly available form, and on this account is a good complete manure. Its value as an all-round fertilizer for all kinds of crops can be materially enhanced by mixing it with mineral superphosphates at the rate of 1 part of the latter to 5 or 6 parts of the fresh manure.

"Such as have a demand for it in a pure state should spread it thinly on trays in a shed, so that it will dry and yet retain its elements. These trays can be built in stacks. In this form fowl manure is valuable for farmers, fruit growers, and gardeners alike. It is also used for tanning. In the fattening districts of southern England there is a demand for air-dried manure at £2 10s. to £3 [\$12 to \$15] per ton, which fairly represents its value, as it has usually a moderate proportion of sand or earth mixed with it. Wherever feasible it should be stored in a covered shed. When dried, the compost named above can be used at the rate of 6 or 8 cwt. per acre of cultivated or fruit land. A useful plan is also to mix 2 parts of moist poultry manure with 1 part of ordinary soil by weight. In this case alternate layers should be made of earth and manure, leaving the whole until both have dried, when it is ready for use."

The fish guano industry of Norway, MAIZIÈRES (*Engrais*, 22 (1907), No. 10, pp. 229, 230).—The present status of this industry is, briefly reviewed and a list of firms engaged in the business is given.

The cultivation of vegetables and the utilization of Paris sewage, D. Bois (*Abstr. in Rev. Gén. Agron., n. ser., 2* (1907), No. 1, pp. 11-13).—The use of sewage in the culture of various vegetables on the sewage farm of Achères is described.

The electro-chemical manufacture of fertilizers, E. F. CÔTE (*Ann. Dir. Hydraul. et Amélior. Agr., Min. Agr. [France], 1906, No. 31, pp. 181-237, figs. 7*).—This is a detailed discussion of the nature of water power and its most efficient utilization in the production of electrical energy to be applied in the manufacture of nitric acid, nitrates, cyanamid, copper salts, and other chemical products, and in the liquefaction of air and the purification of water. The article especially emphasizes the economic importance and possibilities of utilizing water power in the service of agriculture.

A new method for the preparation of lime nitrogen, F. CARLSON (*Chem. Ztg.*, 30 (1906), No. 101, p. 1261; *abs. in Chem. Zentbl.*, 1907, I, No. 6, p. 429).—In the process described calcium fluorid is substituted for the calcium chlorid used in the Polzenius method of preparing nitrogen lime. It is claimed that by this means a nonhygroscopic product is obtained which is much easier to handle and which does not undergo decomposition and loss of nitrogen on standing as is the case with the Polzenius product.

Nitrate of soda from the air, H. DANNEEL (*Umschau*, 11 (1907), No. 12, pp. 225-230, figs. 6).—The Birkeland and Eyde process is described and discussed in its economic aspects.

On the production of nitric acid from ammonia, W. OSTWALD (*Berg-u. Hüttenmänn. Rundschau*, 3 (1906), p. 71; *abs. in Chem. Ztg.*, 31 (1907), No. 10, *Reperl.* No. 8, p. 48).—After briefly discussing different methods of artificial fixation of free nitrogen and the utilization of various materials and waste products in the manufacture of ammonia, the author describes a method which he and E. Brauer worked out in which, by the use of platinum foil and a certain amount of platinum sponge as catalyzers, 85 per cent of the theoretical amount of nitric acid was obtained from ammonia. The application of this process, using gas liquor as the raw material, in a factory at Bochum, Prussia, is described. The possibility of utilizing city refuse in the preparation of ammonia is also referred to.

The nitrate of soda industry of Chile (*Ber. Handel u. Indus.*, 9 (1906), No. 5, pp. 153-200).—This is a report on the development, present condition, and outlook of this industry, by the German consul at Valparaiso.

Nitrate of soda and ammonium sulphate for cereals, KLEBERGER (*Deut. Landw. Presse*, 34 (1907), No. 15, pp. 119, 120).—Comparisons of these two fertilizers on winter rye, winter wheat, and summer oats gave results leading to the conclusion that under certain conditions, particularly on heavy soils with deep subsoils in wet seasons, it is possible to obtain larger yields with ammonium sulphate than with nitrate of soda. It is preferable to use the sulphate in one application before seeding. On spring wheat nitrate of soda is thought to have given better results than ammonium sulphate, the latter apparently delaying the ripening.

Comparative study of the different phosphatic salts contained in superphosphates, R. GUILLIN (*Bul. Soc. Agr. France*, 1907, Feb. 15, pp. 188-192, fig. 1; *Jour. Agr. Prat.*, n. ser., 13 (1907), I, No. 6, pp. 168-171, fig. 1; *Bul. Soc. Nat. Agr. France*, 67 (1907), No. 1, pp. 47-53).—Comparative pot tests on wheat, buckwheat, and leguminous plants, of monocalcium, bicalcium, aluminum, and magnesium phosphates are reported. The conclusions drawn from the results are that bicalcium phosphate is as assimilable as monocalcium phosphate, that aluminum phosphate gives increases in yield comparing favorably with those obtained with calcium phosphate, and that trimagnesium phosphate is as readily assimilated by plants and produces almost the same effects as monocalcium and bicalcium phosphates.

Citric-acid-soluble phosphoric acid in Thomas slag, M. DE MOLINARI and O. LIGOT (*Bul. Agr. [Brussels]*, 23 (1907), No. 1, pp. 50-55, figs. 3).—Comparative pot tests with oats and barley of normal Thomas slag and that which had been digested with 2 per cent citric acid according to Wagner's method are reported. The extracted slag was much less effective on both crops than the untreated material, and the assimilation of phosphoric acid by the plant was much smaller in the former than in the latter case.

Concerning the functions of sodium salts, H. J. WHEELER, B. L. HARTWELL, ET AL. (*Rhode Island Sta. Rpt.*, 1906, pp. 186-316, *dgm.* 1).—The results of

experiments on this subject which have been carried on at the station since 1894 are summarized and discussed in considerable detail in this article. The completion of certain features of the work, particularly the chemical examination of the crops grown with reference to mineral constituents, was made possible by the assistance of the Bureau of Soils of this Department. The work of other investigators bearing upon the subject is reviewed. The details of the plan of the experiment and of the crop yields have been given in previous publications of the station (E. S. R., 17, p. 345).

The results of the experiment to date are summarized as follows:

"These experiments show that in the presence of very limited supplies of potassium salts, sodium salts may greatly increase the yields of certain crops.

"In the case of the mangel-wurzel, similar benefit from sodium salts occurred when as much as 332 lbs. of muriate of potash, or its equivalent of potassium carbonate, were employed per acre. Also, in connection with certain other plants similar though less marked benefit from sodium salts was observed even when the applications of potassium salt were large.

"Sodium salts were found to increase the percentage of phosphorus in the plant. In this respect the carbonate was more efficient than the chlorid. The results furnish much evidence to show that this was an incidental accompaniment of the employment of the sodium salts rather than the cause of the increased growth which resulted. This feature should nevertheless be further investigated.

"Little evidence was secured to indicate that the benefit to plant growth caused by the sodium salts was due to changing the ratio of lime and magnesia in the plants.

"The sodium salts undoubtedly acted as indirect manures by virtue of liberating potash, yet strong evidence was afforded that the potassium taken up by the plant was often more economically utilized, or, in other words, a greater crop was produced when sodium salts were applied in the manures and when relatively more sodium entered the plant.

"The water-culture investigations show unquestionable benefit, under certain conditions, from the employment of sodium salts in the presence of limited supplies of potassium, which is not attributable to liberation of plant food, effect upon soil moisture, etc. This benefit does not seem to be wholly or chiefly explainable upon the ground that the sodium salts had increased the osmotic pressure, for calcium salts failed to have the same marked effect.

"In the dry season of 1899 strong evidence was afforded that applications of sodium salts to the soil prevented the plants from taking up and removing unnecessary amounts of potash, or in other words the sodium seemed to conserve the potassium of the soil. In the wet season of 1901 the contrary apparently resulted. This indicates the necessity of a more careful study of the conditions affecting the beneficial action of sodium salts and the danger of drawing definite and final conclusions from a single experiment.

"The results do not indicate that it would be wise to purposely cut down the supplies of potassium enough to make sodium salts beneficial, for fear of depressing the crops, nor to buy common salt nor sodium carbonate for the purpose of attempting to conserve the potassium in the soil; yet the sodium in the potash salts and in nitrate of soda, which practically costs nothing, may often increase certain crops if a shortage of potassium occurs.

"The results go to show that the beneficial influence of sodium salts is largely conditioned upon the variety of plant, and this is a field of investigation that has as yet remained grossly neglected, not only in this country but also in Europe.

"It is proposed to further study the influence of sodium salts upon the reaction of the medium and the bearing of this influence upon the growth of

plants, also the possible influence of the sodium in changing the ratio of other mineral ingredients taken from solutions by growing plants. In short, it is hoped by these and other means to throw additional light upon the physiological functions of sodium and the practical significance of sodium salts in agriculture.

"A study has been begun of the influence of the application of varying proportions of sodium and potassium salts upon the organic constituents of certain plants."

Fertilizer fertilizers, J. S. BURD (*California Sta. Bul.* 187, pp. 353-382).— "This report gives the results of fertilizer inspection work for the first half of the fiscal year 1906-7." Analyses of 183 samples are reported and discussed. The following deficiencies occurring in 24 samples were found: In available phosphoric acid (total when available is not guaranteed) 7, total nitrogen 16, potash 9, valuation 6.

Fertilizer inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul.* 170, pp. 63-80).—"This bulletin contains the analyses of manufacturers' samples of brands of fertilizers licensed before February 10, 1907."

Inspection and analyses of commercial fertilizers on sale in the State, W. F. HAND ET AL. (*Mississippi Sta. Bul.* 97, pp. 57).—This bulletin summarizes the results of inspection of fertilizers during the season of 1905-6, reporting analyses and valuations of 437 samples, 33 of which were found to be below guarantee in relative value.

FIELD CROPS.

Report of work at McNeill Branch Station for 1905 [Field crops], E. B. FERRIS (*Mississippi Sta. Bul.* 94, pp. 17-29, figs. 5).—The results of a corn fertilizer test seem to indicate that on the unimproved soils of that region the most economical fertilizer for corn is one containing 1 part of cotton-seed meal to 2 parts of acid phosphate, applied at the rate of from 100 to 300 lbs. per acre. During 4 years' work only a slight increase of crop was observed as apparently due to the use of potash salts. Among the different varieties of corn grown Coker Prolific, for the second time, ranked first in yield with 44.6 bu. per acre. In tillage experiments, deep preparation and deep cultivation gave 36.7 bu., deep preparation and shallow cultivation 37.6 bu., shallow preparation and deep cultivation 35 bu., and shallow preparation and shallow cultivation 36.4 bu. per acre. The shallow cultivation consisted in stirring the soil about 3 in., and deep cultivation in stirring it about 5 in. deep.

The yields of different varieties of cotton ranged from 680 to 970 lbs. per acre. The leading varieties, mentioned in the order of their productiveness, were Cooks, Russell Big Boll, King No. 2, Lewis Prize, and King No. 1, all yielding 900 lbs. or more per acre. Drilling cotton in rows $3\frac{1}{2}$ ft. apart gave a somewhat better yield than cotton planted in either 3 or 4 ft. rows. The average of 3 plats with the plants 9 in. apart in the drill was 1,026 lbs. of seed cotton per acre, of 3 plats with the cotton 1 ft. apart in the drill 911 lbs., of 4 plats with the plants 2 ft. apart in the drill 825 lbs., and of 4 plats with the cotton 3 ft. apart in the drill 718 lbs.

Oats sown in the fall of 1904 did not grow very tall, but were unusually heavy-headed and yielded 3,760 lbs. of well-cured hay per acre.

Spanish peanuts planted as late as June 24 produced about as well as those planted 2 months earlier. The following results were secured in a fertilizer test: No fertilizer, 1,472 lbs. of nuts per acre; 50 lbs. of nitrate of soda, 200 lbs. of acid phosphate, and 100 lbs. of kainit per acre, 1,760 lbs. of nuts; 200 lbs. of acid phosphate and 100 lbs. of kainit, 1,792 lbs. of nuts; 200 lbs. of acid phosphate, 100 lbs. of kainit, and 1,000 lbs. of air-slaked lime, 2,016 lbs. of nuts; 200 lbs. of acid phosphate, 1,760 lbs. of nuts; and 100 lbs. of kainit, 1,680 lbs. of

nuts. A measured bushel of these nuts weighed 22 lbs. One-fourth acre fertilized at the rate of 200 lbs. of acid phosphate per acre and planted to Virginia peanuts yielded at the rate of 1,792 lbs. of dried nuts and 3,520 lbs. of well-cured hay per acre, a measured bushel of the nuts weighing 20 lbs.

A fertilizer test with cowpeas was an exact repetition of the test with peanuts, and the yields of hay on the 6 different plats were 1,136 lbs., 2,872 lbs., 2,640 lbs., 2,816 lbs., 2,416 lbs., and 992 lbs. per acre, respectively. Drilling peas at the rate of 80 lbs. per acre yielded 3,520 lbs. of hay per acre, at the rate of 40 lbs. 4,000 lbs. of hay, at the rate of 20 lbs. 3,200 lbs. of hay, and peas in hills 18 in. apart, requiring 16 lbs. of seed per acre, at the rate of 4,000 lbs. of hay.

Brief notes on several other crops grown at the station are also given.

The Essex field experiments, 1906, B. W. BULL and V. H. KIRKHAM (*Essex Ed. Com., County Tech. Labs., Chelmsford, 1906, Apr., pp. 26, figs. 3*).—Among 7 varieties of wheat compared, *Wilhelmina* stood first with a yield of 49.7 bu. per acre, which was $2\frac{1}{2}$ bu. ahead of *Rivett*. *Browick* produced the highest quality of straw, but in yield of straw the difference between the varieties was not very marked.

In 3 cooperative tests with mangolds an average yield of 25 tons per acre was secured. *Yellow Globe* ranked first in yield with 27 tons and $1\frac{1}{2}$ cwt. per acre. In quality *Long Red* stood first, averaging 10.97 per cent dry matter and 5.13 per cent sugar. *Golden Tankard* was not very far behind *Long Red*, but *Yellow Globe* with 9.42 per cent dry matter and 4.25 per cent sugar was much inferior.

The yield of dry matter and sugar per acre showed the following differences at the 3 centers: *Clavering*, 3 tons dry matter and 1 ton 9 cwt. sugar, *St. Osyth*, 2 tons 12 cwt. dry matter and 1 ton 4 cwt. sugar, and *Feering*, 2 tons 8 cwt. dry matter and 19 cwt. sugar. The average yield at the 3 places was 2 tons 13 cwt. dry matter and 1 ton 4 cwt. sugar. The highest quality was secured on plats manured with dung only. The general effect of commercial fertilizers was to lower the quality, but the use of superphosphate seemed to favor the formation of sugar, while the dry matter followed the general rule and suffered a decrease.

Of 5 varieties of sugar beets *Cooper Selected*, *Kleinwanzleben*, and *Vilmorin Improved* were the best sugar producers. *Vilmorin* ranked highest in both tonnage of beets and purity of juice.

Fertilizer experiments with maize were conducted and the results secured showed that a supplementary dressing of nitrate was beneficial, while superphosphate and potash did not materially increase the yield. It is further concluded that leaving out barnyard manure and increasing the nitrate will not give such results in a dry season as a dressing of barnyard manure and a supplementary dressing of commercial fertilizers.

Results of a fertilizer test with peas showed that 10 tons of barnyard manure gave a return in total crop equal to that of 15 tons, and that the use of 5 cwt. of superphosphate, 5 cwt. of kainit, and 1 cwt. of nitrate of soda per acre is equal in effect to a moderate dressing of manure.

Different treatments were proposed for the prevention of a clover disease caused by *Sclerotinia trifoliorum*. The plat receiving 1 tons of ground lime per acre was free from the disease, and it is considered probable that about 10 cwt. of ground lime applied when a tilth is being obtained for the nurse crop or sown on the stubble in the fall will produce equally good effects.

Report of progress in cereal investigations, G. W. SHAW (*California Sta. Bul. 185, pp. 261-312, figs. 4*).—This bulletin describes the movement toward cereal improvement by the State, reproduces an act passed by the State legis-

lature providing for this work and appropriating money for it, together with the provisions of a cooperative agreement with this Department entered into by the station, describes the experiments which have been inaugurated, and reports the results thus far secured.

The field trials are conducted on 2 20-acre sites, 1 at Modesto, Stanislaus County, as representative of the general cereal conditions of the San Joaquin Valley, and the other at Yuba City, Sutter County, representing those of the Sacramento Valley.

In 1904-5 there were planted at Yuba City station 275 standard varieties of winter wheat, 65 standard varieties of durum wheats, 66 hybrid wheats, 65 standard varieties of barley, 12 standard varieties of oats, 2 varieties of einkorn, 2 of emmer, and 21 of corn. With the exception of corn the plantings at Modesto were almost an exact duplication of those at Yuba City. At Yuba City the spring grains made a more rapid growth than the winter grains, and were for this reason better enabled to keep the weeds somewhat in check. The character of growth of the durum wheats enabled them to cope quite successfully with the weeds. Varieties sown in March did quite well, but the heads were not so large nor so well filled as those sown the first week in January. From observations made on harvested wheat at different stages of maturity, it is considered that the grain will be of much better quality if cut as soon after ripening as possible. In rust resistance the common wheats showed a range of from 10 to 85 per cent. In all cases the commonly grown California varieties proved much more subject to rust than No. 1181, Japanese; Nos. 1433 and 1436, Crimean; No. 1558, Turkey; No. 1564, Pesterboden; No. 1698, Allora; and No. 1699, Canning Downs.

Among the 6-rowed barleys under test Beldi and Mariout, and of the 2-rowed, Black Smyrna and White Smyrna were the earliest. Sixty-day oats were the earliest oat variety, while white oats from England gave the best yield. Of the corn varieties planted at Yuba City, Early Tuscarora, Gehu, and Red Dent had nearly matured by the latter part of July. The extremely hot winds during the first week of July injured all varieties of corn which were just tasseling at that time, and none of the varieties produced good ears. It is concluded that except under the most favorable climatic conditions success in corn culture on the uplands without irrigation is very doubtful.

The operations at the 2 stations in 1905-6 are described in detail, and the plan for nursery breeding followed is outlined. The following plantings were made at the Yuba City station: 325 standard varieties of common and durum wheats, 72 U. S. Department of Agriculture hybrids, 66 Kansas hybrids, 60 of barley, 21 of oats, 1 of spelt, 3 of rye, 2 of emmer, 1 of einkorn, and 15 of corn, making a total of 566 varieties under plat tests. In addition to this work field plantings were made and special experiments relative to cereal culture, such as the use of fertilizers for wheat, rotation experiments, change of seed, and the composition of wheat as affected by time of cutting and other factors were also inaugurated. The work at the Modesto cereal station for this season was similar to that undertaken at Yuba City.

At Yuba City the durums in field plantings in most cases surpassed the common wheats, the average yield being 13.19 bu. per acre, as against 9.30 bu. for the upright-growing varieties, and surpassing the Salt Lake Club by $4\frac{1}{2}$ bu. per acre. It was also observed during this season's work that the time of cutting after the grain has reached the hard-dough stage had but little, if any, influence upon the gluten content, for in only 4 out of 8 cases did the earlier cutting show even a slightly higher percentage of albuminoids. A study made at both stations of the change toward a starchy condition seems to indicate that other fac-

tors than the time of cutting after the grain reaches the hard-dough stage are involved.

Investigations on the winterkilling of cereals, *BUHLERT (Landw. Jahrb., 35 (1906), No. 6, pp. 837-887).*—Morphological, anatomical, and chemical studies were made to determine whether the winter resistance of plants may be recognized by outer characteristics, inner structure, or chemical composition.

The morphological work was done with *Johannis* and *Zeeland* rye and *Preussen* and *Eckendorf* smooth square-head wheat. The less resistant varieties were apparently better developed than the more hardy sorts. The dry matter in the parts above ground of *Eckendorf* smooth square head weighed on an average per plant 0.0164 gm., as compared with 0.0150 gm. for *Preussen*, the hardier variety, and for *Zeeland* rye 0.0221 gm. as compared with 0.0176 gm. for *Johannis*. The average weight per plant of the dry matter in the underground parts was as follows: *Eckendorf* smooth square head 0.0216 gm., *Preussen* 0.0192 gm., *Zeeland* rye 0.0177 gm., and *Johannis* rye 0.0134 gm.

The wheat showed the greater root development and the rye the greater leaf development. It also appears that the less hardy varieties had the greater root development, the relation of above to underground substance being on an average as follows: in *Eckendorf* smooth square head wheat 1:1.317, in *Zeeland* rye 1:0.8, in *Preussen* wheat 1:1.28, and in *Johannis* rye 1:0.761. The root length of the less resistant varieties was also greater than in the hardy sorts, the main roots measuring 927 mm. in *Eckendorf* smooth square-head wheat, 873 mm. in *Zeeland* rye, 628 mm. in *Preussen* wheat, and 679 mm. in *Johannis* rye.

The relation between leaf surface and root length was closer in *Eckendorf* smooth square head and *Zeeland* rye than in the other 2 varieties. Measurements also indicated that the leaves of the hardy varieties were relatively longer and narrower than the leaves of the more tender sorts, and this character is believed to assist the foliage in assuming a protective position against frost and also enabling it to lie closer to the surface on uneven ground. The thickness of the leaves of the 4 varieties showed but slight differences.

The anatomical investigation showed that the plasmolytic effect of frost varied considerably between individuals and varieties and also between different species of plants. Plasmolysis as the result of frost was frequently observed in the leaves of grains, while it was not found in pine needles. The use of potassium nitrate solutions in bringing about plasmolysis also showed different degrees of resistance. Winter barley was less resistant to the action of the solution than winter rye, while pine needles were exceptionally resistant.

The chemical study of the juice of normal and frosted plants showed that the composition was about the same, but that through the action of sodium chlorid or zinc sulphate a greater precipitation of albumen was effected in the juice from normal plants. When the juice of normal plants was kept at a temperature ranging from +5° to -40° C. it was noted that chemical changes took place under the action of low temperatures, but that the juice of different plants behaved differently in this respect. The frozen juice upon melting showed a precipitate containing considerable albumen and traces of lime and phosphoric acid. This precipitate was formed in the juice of spring barley at -7°, of winter barley at -12°, and of winter rye at -15°, while the juice from pine needles was subjected to a temperature of -40° for days before precipitation was observed. It was further noted that the albumen of plants little resistant to frost was more readily precipitated in the presence of potassium chlorid, sodium chlorid, and zinc sulphate solutions than the albumen of plants capable of withstanding low temperatures.

Alfalfa growing in Missouri, M. F. MILLER (*Missouri Sta. Bul.* 72, pp. 52, figs. 6, map 1).—The extent of alfalfa culture in Missouri is described and general directions for growing and harvesting the crop are given.

The stiff subsoils of the State are considered responsible for most of the failures with the plant. It has been found that on upland soils that have never grown alfalfa or sweet clover inoculation is a benefit, while on bottom lands or on very fertile soil inoculation has little or no effect. Inoculation by means of inoculated soil is considered the surest and the simplest method. The best time to sow the seed in the State is between the middle of August and the middle of September.

The hybridization of barleys, R. H. BIFFEN (*Jour. Agr. Sci.*, 2 (1907), No. 2, pp. 183-206).—This paper describes experiments on the hybridization of barley commencing in 1901. The history of this line of work is briefly reviewed and notes on the varieties used as parents are given.

The different pairs of characters investigated in numerous crosses of different species and varieties of barley were as follows: Sexless and staminate lateral florets, hermaphrodite and sexless lateral florets, staminate and hermaphrodite lateral florets, hooded or trifurcate and awned paleae, black and white color in the paleae, purple and white paleae, narrow and broad glumes, lax and dense ears, adherent and nonadherent paleae, brittle and tough rachis, awnless and hooded paleae, and a number of minor characters. The correlation of the color of the paleae to the color of the grain was also studied.

Experiments with sugar and fodder beets, T. REMY (*Fühling's Landw. Ztg.*, 56 (1907), Nos. 4, pp. 105-122; 6, pp. 185-202).—These experiments consisted of variety tests of sugar and fodder beets, experiments in transplanting small beets in beet-seed culture, and observations on the food requirements and assimilation of seed beets.

The result of a variety test are summarized in the following table:

Comparative test of varieties of sugar beets.

Variety.	Yield per hectare.		Rank according to sugar production.	Sugar in the beet.	Rank according to sugar content.	Proportion of leaves to crowned beets.
	Beets.	Sugar.				
	<i>Kg.</i>	<i>Kg.</i>		<i>Per cent.</i>		<i>Per cent.</i>
Meyer Friedrichswerth.....	37,200	5,420	4	14.6	8	94.5
Vilmorin française riche.....	36,100	5,350	6	14.8	7	110.6
Brenstedt Elite A.....	34,400	5,480	2	15.9	6
Mette Spezialität.....	34,000	5,410	5	15.9	6	110.4
Heine Vilmorin.....	33,600	5,520	1	16.4	4	129.0
Rieselfeldelite.....	32,900	5,520	1	16.7	2	95.4
Dippe Klein-Wanzleben.....	32,500	5,300	8	16.3	5	121.5
Frühe Klein-Wanzleben Original.....	32,200	5,470	3	17.0	1
Dippe zuckerreichste.....	31,800	5,310	7	16.7	2	93.3
Strube Selhanstedt.....	30,700	5,080	9	16.5	3	124.1

A number of cooperative tests conducted to determine the varieties of fodder beets best adapted to transplanting are described. The general results show that Cimbai Yellow Giant stood transplanting best, with Yellow Lentewitz a close second. It was also found that the weight of the mother beet had but little influence on its value as a seed producer. It is recommended that no more than one crop of transplanted beets for seed be grown between the selected beets and the commercial seed crop. It is believed that the use of small beets for seed culture has a tendency to deteriorate the form, and to overcome this tendency it is advised that greater care in the selection of mother beets according to form and to yield be exercised.

Experiments by other investigators on the food requirements of the seed sugar beet indicate that a yield of 3,000 kg. of seed per hectare removes from the soil 198.7 kg. of nitrogen, 219 kg. of potash, and 32.6 kg. of phosphoric acid, while those by the author indicate that 1,000 kg. of beet seed takes from the soil 38.9 kg. of nitrogen, 67.3 kg. of potash, 15.6 kg. of phosphoric acid, 25.5 kg. of lime, and 14.5 kg. of magnesia. It is stated that the production of 1,000 kg. of beet seed requires about the quantity of plant food necessary to produce 10,000 kg. of beets. The rate of consuming plant food was found to be quite uniform during the entire vegetative period. The rate of growth of the plants was quite closely correlated with the rate of plant food consumption. Only in the early stages of growth the quantity of plant food consumed was a little out of proportion to the growth made by the plant. The period of plant food consumption extended over 153 days.

It was further observed that the seed beet planted at the proper time ceases to take up food about 1 month earlier than the beet grown for sugar. The necessity of a good supply of plant food is greatest in the later period of growth of the seed beet as compared with the medium stage of development in the sugar beet. The period of plant food consumption in the seed beet is about 20 days shorter than it is in the first year of the sugar beet, but the quantity of nitrogen consumed is practically the same. The quantities of potash and phosphoric acid required for the seed beet are much greater than those demanded by the sugar beet, but the sugar beet uses the greater quantities of lime and magnesia.

Field corn in Arizona, V. A. CLARK (*Arizona Sta. Bul. 54*, pp. 122-131, figs. 2).—A number of varieties of corn tested are listed with reference to their resistance to a dry and hot climate and their tendency to attacks of smut and the corn earworm. The nonfilling of the ears is commonly attributed to the drying out of the pollen or silks. The filling of the ear in the varieties tested ranged from perfect filling, as in White Mexican Flint and a few other varieties, to the setting of practically no kernels at all, as in the King of Illinois. The most productive varieties were Chester County Mammoth, Large Yellow Dent, Queen of the Prairie, Griswold Bronze, Mexican White Flint, King Philip, Kellogg, and Blue Squaw. Mexican White Flint is considered the best variety for the region, although Kellogg and Blue Squaw, both flint varieties, also succeeded when it was so dry and hot that dent varieties failed. These 2 varieties are only moderately productive. High-bred strains of corn from the east proved to be more susceptible to attacks of worms and smut, and were more liable not to fertilize than less specialized and less highly selected varieties from the same region.

Brief notes are given of the varieties grown, which include Yellow Dent, White Dent, early Northern flints, and Western flint corns.

The advantage of planting heavy cotton seed, H. J. WEBBER and E. B. BOYKIN (*U. S. Dept. Agr., Farmers' Bul. 285*, pp. 16, figs. 6).—This bulletin presents the results of experiments in the separation of cotton seed, and discusses the advantage resulting from this practice, the importance of using heavy seed, the preparation of the seed, and the method of separation. Both the Sea Island and Upland cotton are described.

After separating the seed into 4 grades, heavy, medium, light, and very light, 500 seeds from each grade were found to weigh as follows: Heavy 81½ gm., medium 77½ gm., light 74½ gm., and the very light 62½ gm. A lot of seed was separated into heavy, medium, and light grades, and equal quantities of the three grades weighed 25¼ lbs., 22¾ lbs., and 20¾ lbs., respectively.

Of seed separated into 4 grades, heavy, medium, light, and very light, 350 seeds from each grade were planted in practically pure sand on March 2, 1906.

On March 16, 228 of the very light, 294 of the light, 273 of the medium, and 305 of the heavy seeds had germinated. In a test of heavy and of unseparated seed at Lamar, S. C., the yield of seed cotton from 20 rows from heavy seed was 103 lbs., or 10.9 per cent, greater than the yield from the unseparated seed. In a test at Hartsville, S. C., the heavy seed yielded 88.3 lbs. of seed cotton, or 8.25 per cent, more than the unseparated seed. It is pointed out that if the seed cotton is rated at 4 cts. a pound the differences in yields obtained at Lamar and Hartsville are approximately \$4.12 and \$3.55 per acre, respectively.

In connection with experiments in 1906 by W. A. Orton of this Department with Sea Island cotton seed in rows of equal length, the germination was as follows: Light seed 188 plants, heavy seed 327 plants, and unseparated seed 237 plants. A lot of 85 lbs. of Sea Island cotton seed, separated on a machine constructed on the plan of that devised and described by the authors of the bulletin, consisted of 76 lbs. of cleaned seed, 7½ lbs. of imperfect seed, and 1½ lbs. of cotton. It is believed that this separation might have been improved by running the cleaned seed through the separator a second time under an increased air blast, as the large percentage of cleaned seed indicates insufficient separation.

Comparative value of whole cotton seed and cotton-seed meal in fertilizing cotton, E. B. BOYKIN (*U. S. Dept. Agr., Farmers' Bul. 286, pp. 14, figs. 2*).—This bulletin discusses the use of cotton seed for a fertilizer, points out the profit to growers by disposing of the seed, suggests methods of cotton seed preservation, and reports the results of experiments conducted for 2 years, in which whole cotton seed and cotton-seed meal were compared as fertilizers for cotton. A dark sandy loam with a clay subsoil was selected for these tests. Forty bushels of seed per acre were compared with 600 lbs. of meal, 30 bu. with 450 lbs., and 20 bu. with 300 lbs.

It is believed that the results "amply justify the assumption that 900 lbs. of meal is at least equivalent to a ton of seed in effect on the crop; that is, on such land as was used for this experiment."

Varieties of cotton, 1905 and 1906, W. R. PERKINS (*Mississippi Sta. Bul. 98, pp. 5*).—This bulletin is a brief report on variety tests with cotton for 1905 and 1906. In 1905 the difference in value of crop between the poorest and the best yield was \$26.81 per acre, and in 1906, \$19.25. In 1905 the leading varieties, based on the value produced per acre, were in the order mentioned: Cook Improved, Toole Early, Layton Improved, Truitt, and Lewis Prize; and in 1906 the 5 leading varieties on the same basis were Cook Improved, Cleveland Big Boll, Eureka, Triumph, and Peterkin.

Cowpeas, A. E. GRANTHAM (*Missouri Sta. Bul. 73, pp. 60, figs. 9*).—It was ascertained that cowpeas can be grown successfully in all Missouri soils, and that as much forage can be produced from this crop in 80 days as red clover will yield in 15 months.

In the southern part of the State cowpeas may be planted with corn and cut together for silage to good advantage. In this part of the State, also, cowpeas may follow wheat or oats and produce a crop of hay or pasture before fall seeding. In northern Missouri this latter practice is successful only in favorable seasons or with an early maturing variety. It is stated that growing cowpeas not only increases the fertility of the soil, but also improves its physical condition, making it more open, friable, more easily worked, and increasing its moisture-holding capacity. The crop is also said to cause the soil to dry out earlier in the spring. The Whippoorwill variety is recommended for general purposes and the New Era for a catch crop or for a short season. When the peas are not to be cultivated 4 or 5 pk. of seed per acre is required, but if cultivation is to be given 5 to 8 qt. will be sufficient.

Experiments made at the station showed that Michigan Favorite, Warren New Hybrid, Warren Extra Early, Grotte, Extra Early Blackeye, and New Era may be classed as early varieties: Early Black, Whippoorwill, Early Boolock, Iron, California Blackeye, and Black as medium early, and Red and Clay as late varieties. One bushel of seed per acre drilled seemed to be the most economical quantity to use, especially when seed is high. The difference in yield of cultivated and uncultivated plats seemed to be clearly in favor of those not cultivated.

A comparison of the meteorological records for June, July, August, and September shows that September is a more favorable month for haymaking than June, there being less rain, more clear days, a higher maximum temperature, and more wind.

The value of the cowpea crop is estimated at \$12.80 per acre when grown for hay, and \$13.75 per acre when grown for seed.

Observations on millets, V. A. CLARK (*Arizona Sta. Bul. 54, pp. 118-121*).—Brief descriptions are given of cultural experiments with German, Hungarian, Hog, Japanese, Texas, and Pearl millets. Pearl, German, and Hungarian millets were most effective in keeping down weeds. In palatability these varieties also seemed to rank first. It is concluded that German millet is the best variety for that climate.

Soy bean varieties, C. R. BALL (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 98, pp. 28, pls. 5, figs. 2*).—The history of the soy bean and its variability are discussed, and the varieties classified in accordance with a key worked out for the purpose. Descriptions of 23 varieties are given, and they are classified according to the color of their seed into black-seeded, brown-seeded, mottled-seeded, green-seeded, greenish-yellow-seeded, and yellow-seeded groups. A list of synonyms is also given.

Investigations on the effect of nitrite and inoculating soil on soy beans, A. STUTZER (*Jour. Landw., 55 (1907), No. 1-2, pp. 78-80*).—These observations were made under pot culture and field conditions. The use of nitrite and sodium nitrate caused a luxuriant development of the plants, and no injurious effect from nitrite was observed. When the plants were taken up in the fall no root nodules were found.

In earlier experiments it was observed that nitrite produced an injurious effect on the germination of red clover seed, but no injurious results were noticed in connection with the germination of the soy beans.

The soil inoculation test was made with soil secured from a soy bean field in Japan. The first year only a few nodules were formed on the roots, but the second year when the crop was sown on the same plat the roots were provided with numerous nodules, showing that the nodule-producing bacteria had successfully survived the winter.

References to recent work in plant breeding, C. FRUWIRTH (*Jour. Landw., 55 (1907), No. 1-2, pp. 143-159*).—References are given to 36 articles and publications reporting work in plant breeding or discussing this subject.

A quick method for the determination of moisture in grain, E. BROWN and J. W. T. DUVEL (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 99, pp. 24, figs. 12*).—A method, with the apparatus required, for making complete moisture determinations of grain in from 20 to 25 minutes is described.

The work reported has reference mainly to the determination of moisture in corn, and the method described consists primarily in heating a definite quantity in an oil bath to drive off the water, which is condensed and measured in a graduated cylinder. The average moisture content of 28 samples of corn, as determined by this quick method, was 17.40 per cent, as compared with 17.26 per cent, the average of the determinations made in a water oven. Whole kernels were used in order to obviate the loss of water due to grinding. It was

found that a sample from the whole kernels gave 26.01 per cent of water, while the ground sample showed only 24.36 per cent. In another test the whole kernels showed 35.68 per cent of moisture and the ground kernels 34.75 per cent. Sixteen samples gave an average of 20.13 per cent for whole kernels and 20.05 per cent for ground kernels, the moisture content of the different samples varying from 12.71 per cent to 35.68 per cent.

The apparatus consists of an evaporating chamber with 2 or more compartments, a condenser, and a stand. One hundred grams of corn are used for the test so that each cubic centimeter of water in the graduated cylinder represents 1 per cent of moisture. When the thermometer in the distillation flask registers 190° C. the gas is turned off, and the reading of the amount of water expelled is made 8 or 10 minutes later. The oil used is a good grade of pure hydrocarbon oil with a flash point of 200° to 205° C. The oil is poured into the flask to first lessen the danger of its being broken by the kernels of corn dropping on the bottom.

Practical suggestions for seed testing, J. J. THORNER (*Arizona Sta. Bul. 54*, pp. 99-102, fig. 1).—An apparatus for testing several kinds of seeds at the same time is described, and a number of purity and germination tests taken from a series of experiments carried on during the last 2 years are given in a table.

Attention is called to the fact that in 1 sample of alfalfa seed 90.6 per cent was pure seed, of which 95 per cent was viable, or 86 per cent of the total sample, while of another sample only 59 per cent was capable of growing. These 2 samples sold on the market for 15 and 16 cts. per pound, respectively. Two other samples sold for 16 cts. per pound, although 1 contained 29 per cent of inert matter. The samples of rye and barley tested were practically free from inert matter and weed seed, while the wheat contained about 9,000 weed seeds for every bushel. A 30 gm. sample of oats tested contained 10 varieties of weeds, represented by 298 seeds.

Seed inspection, C. D. WOODS and R. L. HAMMOND (*Maine Sta. Bul. 138*, pp. 50).—The requirements of the Maine seed law are briefly stated, and the results of the examination of samples of seed in 1906 are tabulated in detail. A list of the weed seeds found in these seeds is also given.

Pure versus poor seed, H. F. ROBERTS and G. F. FREEMAN (*Kansas Sta. Spec. Circ., Jan. 30, 1907*, pp. 21).—This circular compares the cost of obtaining a full stand of alfalfa when pure and poor seed are used, and also reports observations made with reference to blue grass and brome grass seed.

It is pointed out that in 1905, of the 1,018,206 acres devoted to the culture of forage crops, 602,560 acres was in alfalfa, and that the cost of seeding this acreage at the rate of 15 lbs. per acre with seed at 16 cts. per pound, every seed being good, would amount to \$1,446,128, while taking as a basis from among the number of alfalfa seed samples analyzed by the station 28 showing an average of total impurities of 46.1 per cent and an average number of seeds true to name but incapable of germination of 34.5 per cent, it would have cost \$1,935,042 to secure a full stand on the same area. The principal impurities found are dead and defective alfalfa seed itself, trefoil, English plantain or buckhorn, dodder, Russian thistle, crab grass, foxtail, and other weed seeds, and the adulterants are trefoil, bur clover, and sweet clover.

In a certain lot of seed analyzed at the station only 20.2 per cent was pure and capable of germinating. In order to obtain from the use of this pure seed as much of a stand as could have been secured from 15 lbs. of standard seed averaging 83 per cent of the seed true to name and capable of germinating, 73.9 lbs. would have been necessary, and the cost of seeding an acre would have been brought up to \$11.92, as compared with \$2.40 for the standard seed. The 28

samples referred to above ranged in impurities from 21.6 to 100 per cent, in trash or dirt from 0.3 to 31.9 per cent, and in the number of kinds of foreign seed present from 3 to 34 per cent.

The amount of English blue grass seed tested in the fall of 1905 contained less than 50 per cent of germinable seeds, and the percentage of weed seed was so high that on each acre there was sown with this seed 142,230 seeds of crab grass, 111,000 seeds of dock, 393,670 smartweed seeds, 62,340 cheat seeds, together with 111,000 miscellaneous seeds, making a grand total of 820,240 weed seeds of all kinds. The crop harvested from this seed contained only about 15 per cent of English bluegrass seed, while 79 per cent was cheat and such weeds as bindweed, dock, foxtail, and pigweed. A comparison of the different grades of seed estimated and determined by the station is given in the following table:

The cost per acre of standard and poor seeds compared.

Samples.	Good seeds.	Seed required per acre.	Cost of seeding an acre.	Germinable seed, cost per bushel.	Weed seeds per acre.	Weeds per square foot.
	<i>Per ct.</i>	<i>Lbs.</i>				
Alfalfa 201	52.0	28.7	\$4.63	\$19.21	93,910	2
Alfalfa 20	73.6	20.3	3.07	13.58	238,750	5
Alfalfa 215	66.3	22.5	3.63	15.00	313,730	7
Alfalfa 227	42.0	35.7	5.75	23.80	167,470	3
Alfalfa 267	20.3	73.9	11.92	49.26	4,241,950	105
Alfalfa standard	83.3	15.0	2.42	12.00	-----	-----
English blue grass 284	49.3	105.4	1.05	4.05	820,240	-----
English blue grass 375	43.4	120.0	12.00	4.80	36,000	-----
English blue grass standard	80.7	50.0	5.00	2.47	-----	-----
Brome grass 107	49.5	50.0	3.85	3.00	157,000	-----
Brome grass 229	32.4	77.0	8.25	4.65	207,900	-----
Brome grass standard	67.5	25.0	2.68	2.38	-----	-----

The seed law proposed for the State, requiring a guaranty of 85 per cent of germination and imposing a tax of one-fifth of a cent on all seed packets less than 1 lb. and of one-fifth of a cent per pound for all seed in bulk, is discussed.

The destruction of wild mustard by spraying and the influence of the weather on the effectiveness of this method, II. HENNEBERG (*Jour. Landw.*, 55 (1907), No. 1-2, pp. 93-121).—An historical note on the destruction of wild mustard by spraying is given, and the results of a series of experiments are reported.

It is recommended to spray copiously when the wild mustard plants are still quite young and during a period of settled weather.

HORTICULTURE.

Report of the horticultural division, F. W. CARD, M. A. BLAKE, and H. L. BARNES (*Rhode Island Sta. Rpt. 1906, pp. 159-175, pls. 7*).—This is a report of the various horticultural investigations conducted at the station, of which the work on market-garden rotation, soil sterilization, and vegetable tent experiments have been continued from the previous year (*E. S. R.*, 17, p. 861).

An attempt was made to exterminate charlock, or wild radish, from grain fields by spraying with the following solutions: Sixty pounds of copperas in 40 gals. of water, and 12 lbs. of copper sulphate in 40 gals. of water. The copper sulphate was applied June 8 and the copperas or iron sulphate June 14. The charlock was then in bloom and too tall to be effectually reached by the spray with the machine used. Judging from this experiment it is concluded that a spray of copper sulphate of the strength as here used, if applied in the earlier stages of the weed growth, would prove decidedly effective in destroying charlock, with no permanent injury to the grain crop.

A large number of grafting waxes were tested in the spring of 1905, and the formula of 2 parts resin to 1 part beeswax seems to be the best proportion to use. The wax can be made harder or softer by the use of more or less tallow or oil. Adding tallow to the wax does not produce lumps if not used to excess. Adding resin to a soft lumpy wax will render it smooth and pliable.

An extensive experiment was conducted in the summer of 1905 with lawn plats to test the influence of different fertilizers upon the permanence of white clover and certain grasses, and to compare the adaptability of different grasses and mixtures for lawns, golf links, and polo grounds. In all, 33 plats were included in the experiment. Fertilizers were used furnishing an acid, an alkaline, and a nearly neutral residue. The fertilizer ration used in all cases was as follows: Actual nitrogen per plat, 5.14 oz.; actual phosphoric acid, 6.17 oz., and actual potash, 15.42 oz., or at the rate of 50, 60, and 150 lbs., respectively, per acre. Notes are given explaining the character of lawn resulting from the different methods of treatment and varieties of grasses used. This experiment is illustrated by several plates.

The market-garden rotation experiment was designed to compare stable manure with chemicals in the growing of market garden crops, a cover crop being introduced wherever practicable. This experiment was begun in 1904, when the crop consisted of corn followed by beans on one part of the plat and beans followed by corn on the other. The plat receiving chemicals was on August 19, 1904, sown to timothy and clover, a fair amount of which lived through the winter and was plowed under in June, 1905. The stable manure plat received 1 cord of stable manure and the other plat 200 lbs. of chemical fertilizer, or at the rate of 10 cords of manure and 1 ton of chemicals per acre. Dwarf Stone tomatoes were planted upon both plats June 9, 1905, and the yields harvested from these 2 plats at the various pickings are tabulated. The plants upon the plat receiving the chemical fertilizer made a better start and remained ahead throughout the season. The total picking from August 29 to October 11 on the stable manure plat was 996 lbs. 6 oz., while the total picking for the same period on the chemical fertilizer plat was 1,347 lbs. 5 oz. At the end of the season there were 197 lbs. more green tomatoes and 84 lbs. more rotten tomatoes on the stable manure plat than on the chemical fertilizer plat. A larger proportion of ripe fruit was obtained earlier in the season from the use of chemicals than from the use of stable manure, which is believed to be due to the influence of nitrate of soda in hastening the maturity of the tomatoes.

A score card similar to the one used for strawberries has been adapted for raspberries and is shown here containing the scale of points and a key for the description of the plant.

The work with sterilized soil was continued in 1905, in which the methods of treatment were those formerly used (E. S. R., 17, p. 862), and are as follows: (1) Unsterilized, (2) sterilized and handled while hot, (3) sterilized and handled cold, (4) sterilized and sprinkled lightly with rich unsterilized soil to introduce soil organisms, (5) sterilized and treated with nitrate of soda. The work is discussed in detail. The crops used were radishes and lettuce, and the weights at harvesting obtained from the various soils are presented in tabular form. The radishes obtained from the sterilized soil, handled hot, were not only larger, but brighter in appearance, and those secured from sterilized soils, sprinkled with garden soil, were next as to weight. The lettuce in all plats made a very poor growth, and all the lettuce was pulled and the plats replanted with turnips on August 31. Judging from the weight of the turnips, the leaves of which were badly eaten by worms, the roots secured from soils sterilized and handled hot and from those sterilized and handled cold were practically the same. The radishes were succeeded by Marguerite carnations, and the number

of blooms which were picked at different intervals on the various soils are recorded.

In general, it is stated that as far as these tests go no particular gain has resulted from the reintroduction of soil organisms into a sterilized soil by sprinkling with unsterilized soil. Handling the sterilized soil while still hot appears to act beneficially on the crop.

During 1905, cauliflower was the only vegetable grown under tent covering, this vegetable having shown the greatest gain in the previous experiments. The ground outside the tent was very dry and the plants grown inside made a much better start and continued to make a better leaf growth throughout the summer. The ground inside the tent remained moist much longer after a rain than that outside. The yields of untrimmed and trimmed heads secured inside and outside the tent are tabulated. The proportionate net weight of trimmed to untrimmed cauliflower was 56 per cent in that grown outside and 64 per cent in that grown inside. The total weight of trimmed cauliflower was 60 per cent greater under the tent than outside. From the present experiment it appears that it is possible to grow cauliflower under tent covering in weather when it is almost impossible to secure it outside. The temperature readings, taken during the course of this experiment from June 16 to August 8, are here tabulated and show the average temperature during the day to have been nearly 4 degrees warmer inside the tent than outside. In one instance the inside temperature was 10 degrees higher than outside.

Investigations on the culture of asparagus in the vicinity of Auxerre, E. ROUSSEAU and C. BRIOUX (*Recherches sur la Culture de l'Asperge*. Paris: Soc. Encouragement Indus. Nat., 1906, pp. 112).—The authors have made extensive investigations of the culture of asparagus in the department of Yonne. In the present work consideration is given to cultural practices, the control of insect pests and fungus diseases, marketing, and the cost of production. The total cost per acre of one 15-year-old plantation at Charbuy is estimated at approximately \$738.69 and the gross receipts as \$1,293.07, leaving a net income per acre of \$554.38, or about \$36.95 per year.

The authors have conducted an investigation for 3 consecutive seasons at the experiment station for the department of Yonne, and at cooperative experimental farms, to determine the best method for fertilizing asparagus. In the determination of a well-balanced fertilizer formula studies were made and are here discussed of the physical and chemical composition of the soils of that region, the chemical composition of the plant as indicative of its need, and the chemical composition of the manures and compost ordinarily used near Auxerre to determine what complementary ingredients should be recommended.

As a result of these investigations the use of barnyard manure is recommended as a basis for all fertilizers, since it not only furnishes humus and improves the physical texture of the soil, but also aids in the retention of chemical fertilizers which may be added. On light sandy soils with a porous subsoil, the use per acre of from about 220 to 266 lbs. of basic slag, 175 lbs. of nitrate of soda, and 88 lbs. of sulphate of potash is recommended. The basic slag should be applied with the barnyard manure during winter. The sulphate of potash and about one-third of the nitrate of soda may be harrowed in lightly along the rows after the usual rainy period of spring. The remainder of the nitrate of soda should be applied in 2 applications, at the beginning of the cutting season and a few weeks later. On somewhat heavier sandy soils, in which the subsoil contains a considerable clay content, the authors recommend the use per acre of from 175 to 220 lbs. of superphosphate, 175 to 266 lbs. of nitrate of soda, and 88 to 134 lbs. of sulphate of potash. The heavier application should be given when the asparagus is in full bearing, or when it is impossible to obtain a sufficient

amount of stable manure. Although the use of stable manure is recommended in all cases, the following formula has produced good results when used alone: Mineral superphosphate 266 lbs., dried blood or steamed horn 220 lbs., nitrate of soda 220 lbs., and sulphate of potash 175 lbs. The effect of using these manures for several successive years has been to increase not only the quantity of asparagus gathered, but also the average weight and earliness.

Fruits and vegetables, E. B. FERRIS (*Mississippi Sta. Bul. 94, pp. 4-14, figs. 2*).—This is an account of variety and fertilizer tests, together with the marketing of fruits and vegetables, at the McNeill Branch Station for the season 1905. The work is of a similar nature to that of previous years (E. S. R., 17, p. 1066).

No definite conclusions have been reached as to the best varieties of strawberries, although the station uses the Klondyke, Lady Thompson, and Excelsior in its commercial patch. The Excelsior ripens earlier, but is not so good as either of the others when sowed at the same time. Klondyke and Lady Thompson are about equally prolific, although Klondyke is firmer and colors better. Lady Thompson is highly recommended for nearby markets.

In the fertilizer test the mixture used as a unit application per acre consisted of 200 lbs. cotton-seed meal, 200 lbs. acid phosphate, and 100 lbs. kainit, one-half being applied at the first cultivation after the picking season is over and the other half at the last cultivation in the fall. When the 3 fertilizing materials were used in the proportions given above, 2,620 qts. were gathered per acre. This yield was increased to 3,100 qts. where 1,000 lbs. of oyster shells was added to the above mixture. On the plat where the cotton-seed meal and kainit content remained normal and the acid phosphate was left out entirely, the yield was only 1,840 qts., which seems to show a marked effect of phosphoric acid as a food for the strawberry. For 2 years past the strawberry has been the most profitable truck crop grown at the station. The quality of the fruit during the first part of the season was superior to that of the previous year's crops, and this, together with better shipping facilities, made shipments to Birmingham, Chattanooga, Cincinnati, and St. Louis fairly profitable. From a little less than 2 acres 165 24-quart cases were sold, which brought the shippers net returns of \$360. The total yields of good fruit, however, were considerably reduced owing to a hard rain in April.

Fertilizer tests have been conducted since 1903 in an orchard containing 98 Elberta peach trees. The trees came into bearing this year. Although the yield was fairly good, the quality of fruit is said to have been poor owing to attacks by insects. Data are given showing the amounts of the different kinds of fertilizer used and the yield of peaches. The results seem to indicate the preponderating influence of nitrogen rather than phosphoric acid, together with some benefits from potash, which has not been the case with other crops. No difference was noted in the color of the peaches owing to the presence or absence of potash soils under the trees. The peaches were not marketed to advantage, since the various varieties ripened at different intervals.

From the Greensboro orchard, together with some 20 trees of other varieties, were sold 105 crates, which netted the shippers \$110. Sixty crates were sold from the Elberta orchard, netting \$67.50. From the remainder of the crop 35 doz. 3-pt. cans of fruit were put up and disposed of at from \$1.80 to \$2 per dozen. The 6-basket ventilated peach crate is considered the most desirable shipping package. During the winter of 1906, 1,000 additional Elberta trees were set out, with the view of producing carload shipments of fruit.

None of the plums pears, or apples have as yet borne any fruit worth mentioning.

From the experiments at the station the author is of the opinion that it is almost folly to attempt to grow orchard crops without exercising every care possible to prevent insect pests and fungus diseases.

In the fertilizer test with asparagus a mixture of 250 lbs. of cotton-seed meal, 500 lbs. of cotton seed, 405 lbs. of acid phosphate, and 170 lbs. of kainit was taken as a unit application per acre, and gave a calculated yield of 1,168 lbs. of marketable asparagus during the spring of 1905. This yield was reduced when any of the fertilizer constituents in the above mixture were either altered in amount or left out. The cutting began on March 22 and continued until May 2, during which time 43 cases of 20 bunches each were sold, giving the shippers net returns of \$58. The crop was considerably affected by rust.

The fertilizer test with beans was repeated in 1905 and a table is given showing the results in detail. The most prolific variety appears to be the Valentine, and the best fertilizer mixture one which contains 224 lbs. of cotton-seed meal, 112 lbs. of nitrate of soda, and 458 lbs. of acid phosphate per acre.

Notes are also given on a large number of other vegetables, including potatoes, beets, turnips, ruta-bagas, and kohlrabi, which are proving successful market crops. In the fertilizer test with Irish potatoes 10 bu. of Tennessee-grown Red Triumph seed potatoes were used per acre. They were planted February 1 and dug on May 23. A mixture containing 214 lbs. of cotton-seed meal, 100 lbs. of nitrate of soda, 456 lbs. of acid phosphate, and 224 lbs. of kainit was taken as the unit application for an acre, which produced an average yield of 103 bu. per acre. This fertilizer proved better than any other combination tried. A test was made between home-grown Irish potato seed and Tennessee stock under similar conditions of planting, etc., and the northern-grown seed gave a yield of 101 bu. per acre, while the home-grown seed yielded but 70 bu. per acre. In a variety test with Irish potatoes the percentage of perfect stand was determined by actually counting the hills in each plat. Burbank again headed the list, giving a yield of 99 bu. per acre with only 60 per cent of a stand.

The test of different-size seed pieces was continued during 1905, with results similar to that of previous years. One-eye pieces yielded 97 bu. and required 350 lbs. of seed per acre. The yield and number of pounds of seed required increased as the size of the pieces increased, until with whole potatoes the size of hen eggs the yield was 140 bu. per acre, 1,560 lbs. of seed being required per acre. The cut seed sprouted fully 1 week earlier than the whole potatoes. Irish potatoes grown exclusively on the experimental plats yielded about 75 bu. per acre. A test was made of the "Lookout Mountain" potato, which did not appear to be of any real value. Fall Irish potatoes have been tried each year since 1902, but have never made much more than the seed planted.

Prior to 1905 the tomatoes were not successful, since the highest priced early fruit always rotted. In 1905 the tomatoes were sprayed with Bordeaux mixture and a wonderful improvement was noted. It is believed that with 2 or more applications of Bordeaux mixture during the season the rotting at the blossom end of the tomato may be effectually controlled.

First biennial report of the Wyoming State board of horticulture, A. NELSON (*Bien. Rpt. Wyo. Bd. Hort., 1 (1905-6), pp. 56, figs. 29*).—The State board of horticulture was organized chiefly for the purpose of holding, in conjunction with the horticultural societies, public meetings for the discussion of horticulture and kindred pursuits, for the collection of statistics and general information pertaining to the horticulture of Wyoming and elsewhere, and to organize and take charge of orchard, nursery, and fruit stock inspection work.

This report gives an account of the progress which has been made along these lines in 1905 and 1906, together with the Wyoming horticultural law by which

the board was created and the regulations adopted by the board. The nursery law and the work of the inspectors are explained in detail, and brief suggestions are given in regard to orchard culture and the purchasing of nursery stock, together with a list of varieties of all the important tree and small fruits, ornamental shrubs and shade trees recommended for planting in Wyoming. Many of the well-known orchard and shade-tree insect pests and diseases are briefly discussed and a summary by counties is given of the status of horticulture in Wyoming.

In an appendix several spraying formulas are given with brief explanations as to their use and application, with a list of manufacturers of spraying apparatus. The report is illustrated with photographs of specimen fruit trees, orchards, and other horticultural views in Wyoming.

Orchard notes, 1906, W. M. MUNSON (*Maine Sta. Bul.* 139, pp. 51-64, figs. 2).—This bulletin contains a report upon apple orchard experiments in Kennebec County, Me., which have been conducted for several seasons (E. S. R., 17, pp. 972 and 1156). The work included experiments in cultivation, mulching, fertilizing, orchard renovation, top-grafting, and the use of cover crops. Notes are also given on the station's dwarf pear orchard, together with suggestions for the planting and care of such orchards.

In the comparative study of cultivation and mulching, the growth of trees was essentially the same as in previous years, whereas the yield of fruit appeared to be better in some cases from the mulched trees. There were fewer cases of dying out among the Gravensteins on the mulched area than on the cultivated area. This is attributed to the less vigorous growth and better matured wood on the mulched area. The use of stable manure as compared with concentrated fertilizers showed little difference with respect to hardiness. The yield on the unfertilized part of the orchard appeared to be in favor of cultivation. On the fertilized portion of the orchard there was a difference of results depending on the variety cultivated. The Tolmans yielded much better where mulching was employed, while the Gravensteins showed a greater yield under cultivation. Summing up the work of the past 2 or 3 seasons, the author is of the opinion that there is an apparent advantage in the use of stable manure, which, however, is not great enough to warrant hauling it long distances. In this case concentrated fertilizers are more economical and give practically as good results.

In the work of orchard renovation, those trees which received no nitrogen in the fertilizer showed a decided lack of color and weak growth, indicative of neglect, while the plats receiving nitrogen, whether alone or in combination, showed a vigorous growth and a rich green foliage. The plat receiving all 3 elements gave the best results. Nitrogen appeared to be the lacking element in this particular orchard. Tabulated data are given showing the yield per tree in the renovation orchard for each year from 1903 to 1906, inclusive. The continued exhibition of individuality of character was noted as in the previous year. The bulletin includes notes and suggestions relative to the pruning of orchards.

Report of fruit experiment stations of Ontario, 1906, L. WOOLVERTON ET AL. (*Ann. Rpt. Fruit Expt. Stas. Ontario*, 13 (1906), pp. 71).—This consists of a general report of the secretary as to the present condition of the fruit stations, outlines of the work for the past season and proposed experiments for the season of 1907, the financial report of the year, notes on the Dominion conference and the horticultural exhibition, together with a report by P. W. Hodgetts of the exhibit of the fruit experiment stations at the industrial exhibition of 1906, followed by a report of the inspector of fruit experiment stations, H. L. Hutt, and reports from a large number of experimenters as to the behavior of different varieties of orchard and small fruits as tested at various fruit stations throughout the provinces.

A list of varieties of vegetables recommended for general growing in the Province of Ontario is also given, including notes on varieties tested at the Essex vegetable station.

Rouge de Trèves. The best cider apple for export to Germany, M. TRUELLE (*Bul. Soc. Nat. Agr. France*, 67 (1907), No. 2, pp. 187-197).—With respect to apple growing in France, the author is of the opinion that in order to be profitable the grower must export a portion of the crop, and here recommends the Rouge de Trèves as an excellent cider apple, well liked by the German cider manufacturer. An account is given of the origin and area under cultivation of this apple, together with a description of the tree and fruit and tables of chemical analyses made by the author and others in regard to the composition of the fresh fruit, juice, and pulp. This apple is also said to be a good keeper and valued both for preserving and evaporation purposes.

The washing of fruits in formaldehyde, H. DE PARVILLE (*Am. Soc. Hort. Allier*, 11 (1906), No. 12, pp. 298-301).—An extensive review is here given of an article published by the author in the *Journal des Débats* November 8, 1906, in which the experiments of G. Perrier in the sterilizing of apples by washing in a solution of formaldehyde are described.

The object sought was to destroy all germs of fermentation in order that the cider manufacturer might secure absolutely sterile must or unfermented juice, which could then be sown with either pure or selected mixed yeasts to correspond with the nature of the product desired.

With grapes, Pasteur found that the yeast germs accumulated on the surface of the fruit. The present investigator, finding the same to be true with apples, succeeded in sterilizing the fruit by immersing the apples for 15 to 24 hours in a solution containing 4 parts of formalin to 1,000 parts of water. When 8 parts of formalin were used to 1,000 parts of water the sterilization was effected in 5 minutes' time. This method is said to be used by a number of persons in preserving their fruit for the winter, but is not generally used in the manufacture of cider, since it is prohibited by the French food laws.

It is stated that must prepared from fruits sterilized in this manner contains but 0.0001 per cent, or 0.25 mg. of formalin to 100 gm. of the must, whereas many of our ordinary smoked food products have been found to contain from 0.4 to 2.5 mg. per 100 gm. of product.

A method of preventing the rapid decay of ripe fruit (*Jour. Bd. Agr. [London]*, 13 (1906), No. 9, pp. 562-565).—The experiments conducted at Kew in 1905 in testing the preservative properties of formalin for preventing the rapid decay of ripe fruit gave satisfactory results, and together with the method of preserving the fruit in formalin have been noted (*E. S. R.*, 17, p. 768).

A second series of experiments conducted in 1906 served to corroborate the results of the previous year. Aside from the treatment of fruits for preserving, formalin is recommended for the preservation of the winter supply of apples, which may be treated as follows: To 10 gal. of water in a cask or a zinc bath, add 1½ qts. of formalin, mix thoroughly, and immerse as many apples, contained in a sack, as the water will cover. Allow the fruit to remain in the solution for 10 minutes, then remove from the sack and place on a layer of straw or hay, or some suitable substance, and drain until dry. It is claimed that where the apples are intended for storage it is not necessary to immerse them in water after their removal from the formalin mixture.

When apples showing the first stage of apple rot were immersed for a quarter of an hour in a solution of formalin of the strength given above, the spread of the diseased spots was completely arrested, and the fruit kept in good condition for several weeks longer than untreated fruit.

Strawberries and their history, COUNT OF SOLMS-LAUBACH (*Bot. Ztg.*, 1. *Abt.*, 65 (1907), Nos. 3-4, pp. 1-76).—This is an historical study of the literature of the strawberry in respect to its botany, classification, and development of various forms, together with an extensive bibliography.

As a result of this study the author concludes that there are 7 real species of strawberries, which may be classed under 3 principal groups. The *Fragaria hagenbachiana* is believed to be a natural cross of *F. collina* and *F. vesca*. *F. grandiflora* (the pine strawberry) is believed by the author to have developed in Europe as the result of the cultivation of hybrids of *F. chiloënsis* and *F. virginiana*, contrary to the opinion of Bailey, who classes *F. grandiflora* as the variety *Ananassa* of *F. chiloënsis*.

Fundamental principles of modern viticulture, C. HUGUES (*Rivista. A. ser.*, 13 (1907), No. 9, pp. 193-200).—The author is of the opinion that modern grape growing depends upon the establishment of plantations with pure American graft-stocks or direct-bearers, especially in the production of table grapes. Consideration is given to the establishment of vineyards and selections of varieties for different soils, the use of chemical fertilizers and cover crops, and pruning as affecting the quantity and quality of the crop. The methods of planting, cultivation, and subsequent care are also discussed from an economic standpoint.

Reconstitution of the Algerian vineyards with plants resistant to phylloxera, E. VIVET (*Bul. Agr. Algérie et Tunisie*, 13 (1907), Nos. 7, pp. 171-185; 8, pp. 204-211; 9, pp. 229-236, figs. 3).—This article is introduced by an account of the destruction of Algerian vineyards by phylloxera and the attempt to reestablish them by the use of American vines. It consists principally of practical suggestions for the grape growers of the afflicted regions on the various phases of viticulture. Part 1 deals with a discussion of suitable varieties both of graft-stocks and direct bearers with respect to the different kinds of soil, including a study of the pure American species, American hybrids, and French-American hybrids. Part 2 consists of a discussion of nursery and seed-bed practices, including various methods of propagation and grafting, methods of planting, and subsequent care.

The export of table grapes, C. M. MILAN (*Prog. Agr. et Vit. (Ed. l'Est)*, 28 (1907), No. 18, pp. 535-538).—Prior to 1904 it is stated that the bulk of French table grapes was disposed of in Paris, whereas in 1906 over 2,000 tons were exported to various European countries. The author gives suggestions to grape growers for the increase of this export trade by the selection of varieties of a good quality and recommends a list of desirable varieties for planting in different locations.

The importance of silica in viticulture, OBERLIN (*Rev. Vit.*, 27 (1907), No. 696, pp. 425-430).—In the present article the author discusses the importance of the soil as a factor in the determination of the quality of wines, with special regard to its content of soluble silica, and cites many examples to show that the vineyards producing the more noted wines of France and Germany are grown on soils containing a considerable content of silica. The production of high-grade wines on soils which have a low silica content is said to be restricted to a few especially adapted varieties of grapes.

In order to confirm his belief that the presence of silica has an important effect on the quality of wine, the author has conducted several experiments, the first of which was attempted in 1886 and 1887, in which powdered sodium silicate was used as a fertilizer. As compared with the check, the must produced from vines grown on the fertilized plot was shown to have its density increased to the extent of 10 degrees. In 1889 the use of potassium silicate

gave similar results. Both of these fertilizers, however, proved to be too expensive for commercial purposes.

Further experiments were conducted in 1899 at the Oberlin Viticultural Institute at Colmar, in which the author used powdered phonolite obtained from the debris of a stone crusher used in connection with the macadamizing of roads. The powdered phonolite was applied for a period of 4 years, and the results which were noted in 1905 and 1906 are presented in tabular form. The author concludes that it is practically certain that the density of must is greatly increased by the addition of soluble silicates, and states that it remains to be proved whether the use of silica, especially in the form of phonolite, which was found to contain as high as 56 per cent of silicic acid, is not capable of increasing the alcoholic content of the wine, as well as augmenting its other good qualities.

The grape and wine industry in the provinces of Mendoza and San Juan, Argentina. T. CHIAROMONTE (*Bol. Uffic. Min. Agr., Indus. e Com. [Rome]*, 6 (1907), I, No. 5, pp. 489-513).—An account is given of grape culture and the manufacture of wine in these provinces, in which considerable data are presented in connection with various phases of the subject, special attention being paid to the effect of these industries on the sale of Italian wines.

The total area of irrigated vineyards in these regions is given as about 23,227 hectares (57,370 acres). The value of a 3-year-old vineyard is estimated at 1,829 pesos (\$1,765). In Mendoza one-fourth of the grapevines are native and three-fourths of French origin, whereas in San Juan two-thirds of the vines are native and one-third of French origin. The annual production of wine in the Republic of Argentina is said to be about 2,000,000 hectoliters (52,800,000 gals.).

The quality of the different grades of wine is discussed, and tabulated data are given showing the production, importation, and consumption of beer for each year from 1902 to 1905 and of wine from 1894 to 1906.

Extensive and intensive culture of Brazilian coffee trees, C. BOLLE (*Tropenpflanzer*, 11 (1907), No. 2, pp. 69-79).—The author gives an account of the different coffee zones in Brazil, and discusses the relative merits of the cultivation of coffee as the only crop on large plantations as compared with its cultivation in connection with other crops. After a comparison of these two methods he is of the opinion that the culture of coffee may be conducted with profit in either way.

Poppy culture and the production of opium, H. THOMS (*Über Mohnbau und Opiumgewinnung*, Berlin: Borntraeger, 1907; rev. in *Chem. Ztg.*, 31 (1907), No. 24, p. 316).—The author's results in the cultivation of poppies in the experimental fields of the German Institute of Pharmacy at Dahlen during the years 1905 and 1906 are given.

These experiments further demonstrate the facts that the climate and soil are suited for the cultivation of the poppy and the production of opium rich in morphine in north as well as in south Germany. An account is given of the experiments that have been attempted with Prussian, Turkish, and blue and white German poppies with reference to the production of opium and its content of morphine and other opiates, the relative returns from the different varieties, the cost of production, etc. The author states that the production of opium in north Germany is not profitable, but appeals for experiments in the German colonies, since samples of opium in Kwai and west Africa were found to contain a high content of morphine.

What to do with old bulbs, J. DUNBAR (*Gard. Mag. [N. Y.]*, 5 (1907), No. 5, pp. 294, 295, figs. 10).—Directions are given as to the harvesting, cleaning, and storing of such bulbs as tulips, hyacinths, and daffodils when the flowering season is over.

Danger in the repeated repotting of plants, A. PETIT (*Jardin*, 21 (1907), No. 484, p. 118).—The author performed experiments in order to determine the effect of different size pots and repotting on the growth of plants.

Several marigolds were grown in pots 9 cm., 14 cm., and 19 cm. in diameter, respectively, and in open ground. In each case the weight of 8 plants was taken. The growth of the plant was shown to increase with the size of the pot, the growth in open ground being far in excess of that of the pot-grown plants.

An experiment was also conducted with coleus and heliotrope plants, one portion of each being planted in pots of 7, 9, 12, and 15 cm. in diameter, respectively, while the other portion was repotted successively from the smallest to the largest of these pots. In every case, with the exception of the heliotrope growing in the pot 7 cm. in diameter, the average repotted plant weighed less than the plants started in their permanent position. A further experiment appears to show that the greater the number of repottings the smaller is the development of the resulting plant.

FORESTRY.

Forest planting leaflets (*U. S. Dept. Agr., Forest Serv. Circs.* 76, pp. 3; 77, pp. 4; 82, pp. 8; 83, pp. 3; 84, pp. 4; 85, pp. 4; 86, pp. 3; 87, pp. 4; 88, pp. 5; 89, pp. 4; 90, pp. 3; 91, pp. 4; 92, pp. 4; 93, pp. 4; 94, pp. 3; 95, pp. 4).—These leaflets treat of the form and size, habits and growth, economic uses, methods of propagation, planting, cultivation, and care of the following species of trees, which are given in order corresponding with the circular numbers above: Silver maple (*Acer saccharinum*), cottonwood (*Populus deltoides*), hardy catalpa (*Catalpa speciosa*), Russian mulberry (*Morus alba tatarica*), white ash (*Fraxinus americana*), slippery elm (*Ulmus pubescens*), boxelder (*Acer negundo*), white willow (*Salix alba*), black walnut (*Juglans nigra*), tamarack (*Larix laricina*), osage orange (*Torylon pomiferum*), coffee tree (*Gymnocladus dioica*), green ash (*Fraxinus lanceolata*), yellow poplar (*Liriodendron tulipifera*), black cherry (*Prunus serotina*), and sugar maple (*Acer saccharum*).

Forest planting in Illinois, R. S. KELLOGG (*U. S. Dept. Agr., Forest Serv. Circ.* 81, pp. 32, figs. 2).—In this circular are reported the results of an extensive study of forest plantations in Illinois to determine the kinds of trees best adapted for planting in prairie sections.

About two-thirds of the total area of the State was studied, although the work was confined chiefly to the central and northern portions. The results given are believed to be of general application throughout the State and to similar situations in Indiana, Missouri, and Iowa. In all, 117 plantations were visited and 22,500 trees measured. A description is given of the methods of study and species studied. The important features of the studies are presented in tabular form for each species, including location, age, area of plantation, planting distances, number of trees per acre, tree measurements, products, values, and annual income per acre.

Measurements were taken at the experimental forest plantation of the University of Illinois, which was planted in 1871 and covers an area of 13 acres, containing 20 species of forest trees. The best developed species in the plantation are European larch, white pine, green ash, and black walnut. Suggestions, with accompanying diagrams, are given for the planting and thinning of forest plantations and the formation of shelter belts.

Planting on New Mexico forest reserves, F. J. PHILLIPS (*Forestry Quart.*, 5 (1907), No. 1, pp. 11-19).—Suggestions are given as to suitable species and methods for the reforestation of these reserves, together with notes on their present condition. The author concludes that the degree of watershed development and suitable supply of forest products will determine to a great extent the future prosperity of the Territory of New Mexico.

The trees of Great Britain and Ireland, H. J. ELWES and A. HENRY (*Edinburgh: Authors, 1906, pp. XVI+200, pls. 61*).—This is volume 1 of an extensive treatise, in which the authors aim to give a complete account of all the trees either native to or cultivated in Great Britain which have attained or seem likely to attain sufficient size to warrant their consideration as timber trees. About 300 species are to be considered, the most of which the authors state have been the subject of their personal study.

The present volume consists of 2 parts. In part 1 the several species of the following genera are identified: *Fagus*, *ailanthus*, *sophora*, *araucaria*, *ginkgo*, *liriodendron*, *spruce-firs*, *taxus*, *cryptomeria*, *pyrus*, *taxodium*, and *thuya*. The history and distribution of each in various countries are considered and an account is given of the cultivation, soil, and location, together with descriptions of the remarkable trees of those varieties which occur in Great Britain. Attention is also paid to the use of the various trees for timber or other purposes.

Part 2 is devoted to illustrations of the species discussed, including specimen trees and interesting woods and plantations.

Location, date of latest proclamation, and area of the National forest reserves in the United States, Alaska, and Porto Rico (*U. S. Dept. Agr., Forest Serv. [Circ.], Feb. 1, 1907, pp. 4*).—The data indicated in the title are presented in tabular form.

The total number of forest reserves in the United States is 136, with an area of 123,850,161 acres; in Alaska 2, with an area of 4,909,880 acres, and in Porto Rico 1, with an area of 65,950 acres, making a grand total of 139 forest reserves, including 128,825,991 acres.

The timber supply of the United States, R. S. KELLOGG (*U. S. Dept. Agr., Forest Serv. Circ. 97, pp. 16, figs. 2*).—This circular, a brief summary of which has been previously noted (*E. S. R., 18, p. 944*), contains a discussion of the available timber supply of the United States and the length of time it will last at the present rate of cutting. A large number of statistics are brought together from different sources as to the annual output of forest products, the lumber cut, the geographical distribution of the total lumber product, and estimates of the stumpage of the United States at various periods, together with a recent estimate of the stumpage of the Pacific coast.

A map is given indicating the general distribution and character of the original forests of the United States, which shows the natural timber areas of the country to be embraced in 5 groups of States, as follows: Northeastern States, Southern States, the Lake States, the Rocky Mountain States, and the Pacific States. In the 2 latter groups practically all the timber-producing trees are coniferous, while in the first 3 groups both conifers and hard woods are found.

Four types of forests are produced in the Southern States. The swamp areas of the Atlantic and Gulf coasts furnish cypress and hard woods, and the plains from Virginia to Texas southern or yellow pine. Pure hard woods are found in the plateau encircling the Appalachian range, while the higher ridges contain spruce, white pine, and hemlock. The Lake States still contain many hard-wood forests in the southern portions, and pine, tamarack, cedar, and hemlock in the northern areas. The chief timber trees of the Rocky Mountain forests are western yellow and lodgepole pine, and those of the Pacific forests are Douglas firs, western hemlock, sugar and western yellow pine, redwood, and cedar.

The author asserts that it is unquestionably safe to say that our present annual consumption of wood in all forms is from 3 to 4 times as great as the annual increment of our forests. A chart is given showing the course of prices of white pine, yellow poplar, and hemlock since 1887 and of yellow pine since 1894. The most liberal estimate as to the wooded area of the United States

places it at 700,000,000 acres, whereas it is estimated by others as low as 500,000,000 acres. From a table showing the extent and ownership of forest areas in this country it appears that only one-fifth of our forest area is in National or State forests, the remainder being either in private hands or likely to pass into private hands. It is estimated that the present cut of forest products requires at least 20,000,000,000 cu. ft. of wood, and that under the present conditions of mismanagement the average annual increment is less than 10 cu. ft. per acre for the entire area, whereas an annual increment of 30 cu. ft. per acre is required to maintain the supply of timber now consumed annually.

The bulletin concludes with several quotations from an article by Fernow on the financial management of forests in Saxony and Prussia (E. S. R., 18, p. 741), with reference to the adoption of a settled policy of forest management, based upon the cutting of the increment only, without lessening the wood capital.

The lumber industry in the mountains of British Columbia, F. W. JONES (*Canad. Forestry Jour.*, 3 (1907), No. 1, pp. 31-32, pl. 1).—In this paper, read before the forestry convention, Vancouver, September, 1906, consideration is given to the needs of the lumbering industry in relation to forest preservation. The author discusses the existing forest regulations and offers suggestions for the betterment of laws dealing with fires, the securing of more definite regulations covering the difference between agricultural and timber lands, the inauguration of a campaign of education as to the importance of preserving standing timber, and an amendment of the provincial regulations in order to provide for such tenure and terms on timber licenses that the lumbermen will be able to pay some attention to forestry principles in carrying on their operations.

Notes re timbers of Western Australia suitable for railways, engineering works, and constructional purposes generally, N. J. MOORE (*Perth: Govt.*, 1906, pp. 36, figs. 17, map 1).—These notes include a discussion of the timber resources of Western Australia, forest areas and distribution, brief general descriptions of the principal trees and timbers, the available supplies of timber for commercial and other purposes, the economic uses of the principal timbers of the State, their physical characteristics, and their resistance to the teredo, white ant, and dry rot.

A report is also given by the chief engineer of existing lines, W. W. Dartnall, on the use of Western Australia hard woods for railway ties. The species of timber chiefly used is Jarrah (*Eucalyptus marginata*). The total number used on railways, including renewals, has been from 4,000,000 to 5,000,000. The present size of the sleeper is 7 ft. by 9 in. by 4½ in.

The text is accompanied by statistical data in regard to the climate of Western Australia, timber exports from 1895 to 1904, the strength of Western Australia timbers, information concerning timber shipping ports, forest working laws, and several illustrations of Western Australia trees and lumbering operations, together with a sketch map of the southwest portion of Western Australia, showing the approximate position of the principal timber forests.

Quantity and character of creosote in well-preserved timbers, G. ALLEMAN (*U. S. Dept. Agr., Forest Serv., Circ. 98*, pp. 16, figs. 2).—Recent reports on the service of creosoted railroad cross-ties and piles placed in salt water are said to show clearly that while proper treatment gives remarkably good results, much of this timber was improperly treated and has not lasted as it should.

This circular contains an account of the results, together with a description and discussion, of a series of analyses of the oils present in such forms of creosoted timber as have given long service. The work is introduced by a brief account of the source, composition, and production of coal-tar creosote. Numer-

ous statistics are also given as to the production and importation of creosote at different periods since 1898, from which it would appear that about 7,700,000 gal. of creosote oil were used in this country in 1903 for the impregnation of timber. This amount increased to about 8,650,000 gal. in 1904, and to 13,550,000 gal. in 1905. A description is given of the methods of extracting creosote from timber and analyzing the extracted creosote.

Analyses were made of 37 samples of wood, consisting of railroad ties, piles, and paving blocks of English and American origin, and one sample of conduit pipe. The analytical results are tabulated and discussed.

Woods used for packing boxes in New England, J. P. WENTLING (U. S. Dept. Agr., Forest Serv. Circ. 78, pp. 4).—In this circular, statistics compiled from answers to questions sent to box manufacturers throughout New England are given, showing the kinds, quantity, and value of wood used in 344 box factories in the 6 New England States during 1905.

The white pine is the leading box material of New England, furnishing 81.8 per cent of a total consumption of 600,493,000 board ft., or more than 4 times as much as all other kinds combined. Spruce, which is used largely in the manufacture of butter boxes, comes next with 9.9 per cent. The other woods used are hemlock, beech, birch, maple, fir, poplar, chestnut, and basswood. The consumption of 138 factories in Massachusetts was 290,226,000 ft. of lumber, or nearly as much as the 5 other States combined. The total cost reported was \$7,871,500, of which white pine comprised \$6,463,500, or 82.1 per cent. The average cost per 1,000 ft. for each species is given.

“Wood to be suitable for high-grade box making must be strong and tough, so that it can be utilized without splitting; light, to facilitate handling and lessen freight charges; odorless, so that it will not taint the contents of the box; and preferably light in color.” Since white pine largely meets these conditions, is easily worked, and seasons well, it is considered the ideal wood for the box maker. Box manufacturers of New England depend for their supply of lumber mainly upon the farmers' woodlots, and it is believed that if the cut of the available stand continues at the present rate the supply will be exhausted before the present young growth reaches a marketable size.

In order to illustrate the possibilities of forest growth in New England a table is given showing the areas of farm, forest, brush, and waste land in the different States. It is believed that the 10,000,000 acres of waste land, which at present is yielding scarcely any return, if forested and properly managed would eventually yield each year more lumber than the entire cut of white pine in New England in 1905. Suggestions for increasing the supply of white pine in New England have been previously noted (E. S. R., 16, p. 57; 17, p. 772).

The control of forest fires at McCloud, California, A. W. COOPER and P. D. KELLETER (U. S. Dept. Agr., Forest Serv. Circ. 79, pp. 16, fig. 1).—In 1904 the Forest Service, in cooperation with the State of California, made a thorough study of forest conditions in their relation to fire on the tract of the McCloud River Lumber Company, in Siskiyou County, California, with the primary object of devising a practical scheme of fire protection, particularly for the logged lands on which fires are most prevalent. The results of this study showed that adequate protective measures could be carried out at a cost justified by the benefits obtained, and a plan of protection was prepared and submitted to the company.

This circular contains a description of the tract in question, with reference to its area and timber content, notes as to the causes and effect of forest fires, and a description of the plan as submitted and as executed by the Forest Service in cooperation with the lumber company. The plan included the construction of fire lines, a telephone and patrol system, and the equipment of a

tool station, at an estimated cost for the first year of \$645 per township, or about 3 cts. per acre. In beginning the work about 15,000 acres were set apart for protection, but owing to the contour of the country about 70,000 acres were actually patrolled. The patrol of the 70,000 acres cost less than one-half cent per acre. The total cost for the 15,000 acres, including construction of fire lines, was 2 cents per acre. Based on the year's work the estimated total cost of the protection for a period of 40 years is given as \$1,634.92 initial expense and \$542.88 annual expense thereafter. The probable net returns from the experimental area at the end of 40 years are presented in tabular form, in which the price per acre is estimated at \$3, \$4, \$5, and \$6, respectively, and the interest on the investment compounded at 3, 4, and 5 per cent, respectively. At the interest rate of 5 per cent and the valuation of only \$3 per acre for stumpage it is figured that the net receipts will be over \$45,000.

In conclusion the authors state that fire protection as practiced at McCloud has met with success, but that each tract offers local conditions of its own which must largely determine the character of the plan.

DISEASES OF PLANTS.

Results of experiments to test the adhesiveness of some copper fungicides, W. KELIOFER (*Ztschr. Pflanzenkrank.*, 17 (1907), No. 1, pp. 1-12, pl. 1).—A series of experiments was carried on to test the adhesiveness of a number of copper fungicides. Grape leaves were sprayed with fungicides containing calculated amounts of copper, after which they were allowed to dry for 24 hours. The leaves were then split along the midrib and one-half subjected to artificial rain for an hour or more. Both halves were analyzed, and the differences in the amount of copper expressed in percentages were taken to represent the amount or proportion of adhesiveness.

In the first series, after subjecting the leaves for one hour to a rainfall amounting to 20.4 mm., the proportions of the fungicides still remaining were as follows: Copper sulphate solution 9.7 per cent, azurin 44.7 per cent, 2 per cent Bordeaux mixture 60.7 per cent, Bordeaux mixture in which 1 part of lime to 2 parts of copper sulphate was used 67.8 per cent, Bordeaux mixture in which 3 parts of lime to 2 of copper sulphate was used 38.1 per cent, Burgundy mixture slightly alkaline 68 per cent and strongly alkaline 40.7 per cent.

The addition of sugar at the rate of 100 gm. to each hectoliter of solution was tested with Bordeaux mixture, Burgundy mixture, and neutral and basic verdigris solutions. The Bordeaux mixture was less adhesive when sugar was added, but little difference was noted due to its addition to Burgundy mixture or to neutral verdigris, while its addition to the basic verdigris solution greatly increased the adhesiveness of the fungicide.

When subjected to a light rainfall amounting to 16.9 mm. in 24 hours the adhesiveness of the Burgundy mixture seemed greatly reduced, while the precipitate formed by Bordeaux mixture was less affected. This was attributed to changes induced by atmospheric phenomena, especially the presence of ammonium nitrate and carbonic acid in the air. A number of glass plates were sprayed with Bordeaux mixture and Burgundy mixture, and after drying were washed with water containing ammonium nitrate and carbonic acid, with the result that less of the Bordeaux mixture was removed than of the Burgundy mixture. The carbonic acid in this experiment removed more of the fungicide than the ammonium nitrate. In both cases the adhesiveness was in proportion to the alkalinity of the fungicide.

In concluding his investigations the author recommends for practical purposes spraying with Bordeaux mixture which is made slightly alkaline by an excess of lime.

Report of the botanist for 1906, G. P. CLINTON (*Connecticut State Sta. Rpt. 1906, pt. 5, pp. 307-368, pls. 16*).—The author reports on miscellaneous fungus diseases, experiments to prevent onion brittle, the dry rot fungus, and the root rot of tobacco.

A number of diseases that were more or less injurious are briefly described, and notes given on others which are either but recently recognized as occurring in the State or which have only recently become of economic importance. Among the latter class a description is given of an injury to the apple tree caused by the joint effect of freezing and attacks of canker (*Spharopsis malarum*). A leaf scorch of beans which resembles in some respects a bacterial blight, but which failed on examination to reveal either bacteria or fungi, is briefly described, as are also a leaf spot of carnations, due to *Alternaria* sp., the black rot of cauliflower (*Pseudomonas campestris*), and the black mold of corn, caused by *Cladosporium zea*. Notes are given on the bitter rot of the grape and on the shelling of grapes which is usually attributed to some non-parasitic causes. The author states that in connection with this disease he has found the fruiting stages of a species of *Macrophoma*, but for the present the fungus is considered to be a saprophyte.

A yellowing of the leaves of oats, probably due to unfavorable weather conditions, is briefly described, and an account is given of a physiological trouble of peaches which resulted in an early defoliation of the trees. A root injury or rot of peonies, due to an undetermined cause, is said to have been quite serious, and the author records its occurrence and will continue his studies upon it. The leaf blight of pine due to *Hypodermia desmazierii*, pine rust, and winter injury of white pine trees are briefly characterized. An account is given of the wilt of raspberries, due to the fungus *Leptosphaeria coniothyrium*. This wilt developed rather suddenly during wet weather in June, and an examination showed the presence of the fungus at the base or underground portion of the plant. Subsequent investigations showed that it also attacked the berries, spreading from berry to berry in a cluster, and the author is of the opinion that the infection in this case took place in the flowers and very young fruit, the spores being carried by bees or other insects. Spraying experiments were conducted for the control of this disease with but little effect.

A number of diseases of tobacco are described, among them the bed rot (*Corticium vagum solani*), a bacterial canker, damping off, root rot caused by *Thielavia basicola*, and a stem rot. The bed rot, which was more or less troublesome, resembles in some respects the disease attributed to *Sclerotinia* in the previous report (E. S. R., 18, p. 48). While considerable injury is done by the *Rhizoctonia* stage of *Corticium*, the more common damping off agent in the seed beds of the State is said to be *Sclerotinia*. For the control of the stem rot or damping off, the writer suggests sprinkling or spraying the tobacco beds where the disease is present with a weak solution of formalin. If used at the rate of 1 part to 1,500 of water the disease may be kept in check without serious injury to the seedlings. The sterilization of the soil by soaking with stronger solutions or by heat is also recommended.

A white spot of turnips, due to *Cercospora albo-maculans*, a leaf spot of Russian vetches caused by *Ascochyta vicia*, and an anthracnose of violets attributed to *Marsonia viola*, are described.

A series of experiments was carried on to prevent onion brittle, a description of which is given in the previous report of the station (E. S. R., 18, p. 48). The experiments for the control of this disease were carried on in a field where it had first appeared 2 years before, and the treatments consisted of the application of formalin at the rate of 1 to 240 parts of water, limoid at the rate of 700 lbs. per acre, sulphur and limoid, and a complete fertilizer. In each case

after the seed was sown, the fungicide was sprinkled or scattered over it and the adjacent earth before covering. The fertilizer was scattered directly over the rows after the seed was covered. At the time of the harvest the yield of the different plats was as follows: Check plat 121 bu. per acre, formalin treatment 205, limoid 202, sulphur and limoid 191, and complete fertilizer 15. Another series of experiments was conducted in which similar treatments were given plats of onions after the disease had made its appearance, but in no case was any appreciable benefit found that could be attributed to the use of the remedy. While these yields are not equal to the average during a favorable season, yet for the treated plats they were greater than the average yield in the best untreated, uninfected areas.

A study was made of the dry rot fungus (*Merulius lacrymans*), the author's attention having been called to its rapid spread in the timber of a building. The nature of the injury, character of the growth, and damage caused are described, after which the preventive measures which were suggested are outlined. These consisted in the removal of the infected woodwork, provision for drainage in order that the walls of the building should not become damp, and spraying the portions of the building where the wainscoting had been removed with formalin and carbolic acid.

Particular attention during the past season was given to the root rot of tobacco (*Thielavia basicola*). This disease has become a serious pest in certain fields in Connecticut, and while probably not new, has only recently attracted the attention of tobacco growers. The history of the fungus, its nature, distribution, etc., are given at some length, after which an account is presented of the investigations carried on in Connecticut. In some respects the fungus resembles the damping off in the seed bed, but it is quite distinct from it in that the root rot develops almost entirely under ground, attacking the roots and underground portions of the stems. The grower first notices the presence of the disease by his plants failing to make normal growth and their unhealthy, dark-green color. An examination was made of fields and seed beds in a number of localities throughout the State, which resulted in the discovery that the fungus is widely distributed. Experiments were conducted both in the seed beds and in the fields for the control of this trouble, and following the recommendations of A. D. Shamel of this Department, who is cooperating with the station in tobacco investigations, sprinkling the seed beds with a solution of formaldehyde, 1 to 2,000 of water, was tested without much effect. The sterilization of the soil, either by the use of stronger solutions of formaldehyde or by steam, it is believed would be an efficient method of combating this disease in the seed bed. In the fields the experiments were carried on to test the effect of transplanting diseased plants, the effect of transplanting healthy plants into infected soil, and the effect of environment on the development of the disease. There appears from the results of the experiments to be no reason why the best plants from infected beds may not be safely transplanted to the fields, but those which have been to any extent attacked by the fungus should not be transplanted. The setting of healthy plants in infected soil showed that the disease was readily transmitted from the soil to them, and it was found that the character of the soil, subsoil, season, drainage, humus, and the kind of fertilizer, all have much to do with determining the amount of injury caused by the fungus. Based upon the investigations of the one season, the author suggests various measures for preventing the spread of the fungus and injury due to it.

The report concludes with a list of references to the literature relating to this root rot.

Alfalfa root rot, J. J. THORNER (*Arizona Sta. Rpt. 1906, pp. 160-162*).—Alfalfa throughout southern Arizona is said to be subject to a root rot which is

due to attacks of an underground fungus causing the plants to die out in well-defined, usually circular areas or spots. Upon examination the tap roots are found to be diseased and commonly in a well-advanced stage of decay, so that with a little effort they may be pulled from the ground to a depth of 12 to 20 in. The attack of the fungus upon the roots usually stops a little below the surface of the ground, leaving attached to the crowns one or more uninjured root stubs. During hot, dry periods, such as occur in that region, the plants quickly die from inability to absorb moisture.

The first sign of disease on the plants is characterized by the yellowing or wilting, and upon careful examination there will be found distributed over the surface of the roots numerous sterile filaments which frequently form masses of dark-brown mycelium. The fruiting or spore-bearing stage of the fungus is said to develop discontinuously upon the ground along the outer margin of the zone of dying plants and immediately above the matted mycelium. The spore-bearing portions are described as flattened, cushion-like, filamentous masses, 2 to 10 in. or more in extent and $\frac{1}{4}$ in. in thickness. During the younger stages this mass is a creamy-white color, but in age becomes yellowish-brown and breaks up into a fine, powdery spore mass. The sterile mycelium is technically described and measurements are given for the spores. It appears that the spores retain their power of germination for at least a year. So far as this publication is concerned, the fungus has not been definitely identified. It is believed that resistant strains of alfalfa may be obtained to use in seeding infected areas.

Potato scab, W. J. MORSE (*Maine Sta. Bul.* 141, pp. 81-92).—According to the author, the amount of potato scab is rapidly increasing in various portions of Maine, and the object of the bulletin is to warn growers of the gravity of the situation, and to suggest methods for control of the disease. After describing the cause of the scab, the conditions favorable for its development, and the management of infested soils, the author describes the formaldehyde treatment both in the form of gas and as a disinfecting solution for the prevention of the scab. For large quantities of seed he recommends the use of formaldehyde gas generated by the use of potassium permanganate as the most practical disinfecting agent.

The effects of some fungicides recommended for the prevention of stinking smut on the germination of wheat, G. L. SUTTON and J. T. PRIDHAM (*Agr. Gaz. N. S. Wales*, 18 (1907), No. 3, pp. 235-253, figs. 10).—The authors carried on a series of experiments in plats, boxes, etc., to determine the effects of fungicides on the germination of wheat under various conditions of experimentation.

In the first series 18 varieties of wheat were treated with hot water, formalin, copper sulphate, copper sulphate solution and slaked lime, and copper sulphate solution and lime water to determine whether the treatment would have an injurious effect on seed grain. From the tabular statements presented it is seen that the germination was retarded to some extent by the different treatments in the following order, beginning with the treatment which retarded the germination least: Formalin, copper sulphate and slaked lime, copper sulphate and lime water, hot water, and copper sulphate. The ameliorating effect of lime used after the copper-sulphate treatment is clearly indicated by this experiment, and the authors recommend its use either in the form of slaked lime or lime water whenever seed is treated with copper sulphate.

A second series of experiments was conducted to ascertain whether it is advisable to treat the seed just prior to planting or whether it may be done with safety some time before planting. These experiments were divided into two parts. In one the seed was spread in the sun and dried immediately after

treating, while in the other the seed was not dried but was hung in bags in an open shed so that the superfluous moisture would drain away. The results obtained are not altogether conclusive, as beyond the fact that the seed treated with hot water became moldy and half rotten but little effect was noted which could be attributed to the treatment.

In testing the relative merits of the different treatments for the prevention of smut, formalin and copper sulphate treatments were used, and the efficiency of the copper sulphate was found to be in proportion to the strength of solution. Where copper sulphate in the proportion of 1 part to 100 was used its efficiency was about the same as where formalin was employed.

A series of experiments to determine whether formalin or copper sulphate treatment would prevent reinfection with smut was carried on with a number of varieties of wheat, in which the seed was treated and afterwards infected by the introduction of a large number of spores of the fungus. This series of experiments indicated that the protective layer or film of copper about the seed is quite beneficial, while formalin, as a protection against reinfection, has but slight effect.

In experiments to determine the effect of the different fungicides on seed grain when planted in ground too dry for the seed to germinate, the results varied with the different varieties. It appears that for seed lying dormant in dry soil for a period of 4 months there is no need of a protective film such as would be deposited by the fungicide.

Ustilago maydis on the adventitious roots of corn, J. CHIFFLOT (*Compt. Rend. Acad. Sci. [Paris], 144 (1907), No. 14, pp. 764-766*).—The author reports having observed on the adventitious roots of maize undoubted evidences of corn smut, and by inoculations he was able to produce the hypertrophied tissues characteristic of the presence of the fungus.

The raising of strains of plants resistant to fungus diseases, E. E. SALMON (*Report of the Third International Conference, 1906, on Genetics. London: Roy. Hort. Soc., 1907, pp. 378-384*).—The author calls attention to the desirability of investigators devoting their work more largely to the raising of cultivated plants which are resistant to fungus diseases, and points out the varying susceptibility of different individuals to parasitism. He also states that different varieties of cultivated plants show very different constitutions with respect to fungus diseases, and that where such constitutional characters have been tested they have been found to be fixed for the species, variety, or race, and to transmit their immunity or susceptibility to their progeny, the characters appearing unchanged in the hybrids.

Ascogenous forms of Gloeosporium and Colletotrichum, C. L. SHEAR and ANNA K. WOOD (*Bot. Gaz., 43 (1907), No. 4, pp. 259-266*).—On account of the importance of better information regarding the life histories of fungi, the authors studied a number of forms and have succeeded in growing both the conidial and ascogenous stages from 8 different hosts, as follows: *Gloeosporium rufomaculans* from grapes, *G. fructigenum* from the apple, an apparently undescribed *Gloeosporium* from the cranberry, *G. elasticæ* from the leaves of the rubber plant, a form from the honey locust, one from *Ginkgo biloba*, *Colletotrichum gossypii* from cotton, and *C. lindemuthianum* from cultivated beans. Of these the ascogenous form of only one had been hitherto reported.

The authors found that in attempting to make pure cultures they would frequently fail to secure the ascogenous form, but that once obtained it could be successfully grown on various media and under various conditions for several generations.

Heretofore forms of these fungi occurring on different host plants have been regarded as distinct species, but the authors' studies have led to the conclusion

that they can not be successfully segregated as species, as they were unable to find differences other than the host plant of sufficient constancy or importance to distinguish the species or even varieties. On this account the authors are for the present disposed to regard the various forms as varieties of one species, and for reasons presented they refer them all to *Glomerella rufomaculans*, which was originally described from specimens from the grape. A brief account of these investigations has been given elsewhere (E. S. R., 18, p 946).

An account of the genus Pythium and some Chytridiaceæ, E. J. BUTLER (*Mem. Dept. Agr. India, Bot. Ser., 1 (1907), No. 5, pp. 161, pls. 10*).—A monographic study is given of the genus Pythium, in which the biology, phylogeny, and systematic relations are described. Most of the species are said to be saprophytic, although some have become hemiasaprophytic, causing destructive plant diseases. In this respect they resemble parasites, although their best development occurs when living as saprophytes.

Observations are given on some Chytridiaceæ which are parasitic on aquatic Saprolegniaceæ, etc., and a number of new species of the different genera are described.

Diseases of fruit and fruit-bearing plants (*London: Bd. Agr. and Fisheries, 1906, pp. 13, charts 7*).—A series of colored charts with explanatory text illustrating and describing the gross characters of a number of the more prevalent fungus diseases of fruits and fruit-bearing plants, and giving suggestions for their control or eradication. The charts are intended for hanging in school or lecture rooms, and the diseases illustrated are strawberry leaf-spot, strawberry mildew, apple rot, cherry scab, apple mildew, apple canker, heart-wood rot, tree-root rot, bladder plums, peach leaf-curl, shot-hole fungus, leaf blight, apple scab, pear scab, brown rot, vine leaf-blotch, vine leaf-scorch, black rot of vine, powdery mildew of vine, pear leaf cluster-cups, apricot rust, American gooseberry disease, walnut leaf-blotch, cherry leaf-blotch, hazel mildew, and silver leaf.

The scab of apples and pears, E. VOGES (*Deut. Landw. Presse, 34 (1907), Nos. 33, pp. 276, 277; 34, pp. 284, 285; 35, pp. 290, 291, figs. 17*).—An account is given of the biology of the species of Fusicladium that cause the scab of apples, pears, and cherries. The organisms are described at length and the methods by which they gain entrance to the host plant, the effect produced on the hosts, the methods of propagation of the fungi, and the susceptibility of varieties to infection are all treated at some length.

The perennial mycelium of pear rust, K. VON TUBEUF (*Naturw. Ztschr. Land u. Forstw., 5 (1907), No. 4, pp. 217-219, fig. 1*).—The author figures and describes the appearance of the acedial stage of pear rust on shoots of trees where the mycelium must have been perennial, as the time of occurrence and location seem to indicate that it had wintered on the host plant.

Oidium or powdery mildew of the vine, F. T. BIOLETTI (*California Sta. Bul. 186, pp. 315-352, figs. 17*).—A description is given of the Oidium or powdery mildew of the vine, which is due to the summer or conidial phase of *Uncinula spiralis*. This disease, according to the author, is one of the most serious fungus diseases to which grapes in California are subject.

After describing the fungus and its effect upon the host plant, the author gives accounts of the methods of treatment, the application of sulphur, it is claimed, being the most efficient. Methods of training, cultivation, and irrigation which keep the vine dry minimize the danger of attack. The weather and season when the sulphur is applied are of great importance, and the number of treatments will vary with the locality, season, and variety. The cost of the sulphur and its application will vary from 50 cts. to \$2.25 per acre, depending upon the form of apparatus and the fineness of the sulphur. Thus far

American makes of machines have been found inferior to some obtained in Europe, which are especially adapted to the distribution of sulphur.

Rose canker, P. SORAUER (*Ztschr. Pflanzkrankh.*, 17 (1907), No. 1, pp. 22-32, pls. 2).—A form of canker observed on Crimson Rambler and other roses which appears as a result of frost injury near the base of the stems is described. A similar injury is also reported upon various spiræas.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Recent progress in the study of variation, heredity, and evolution, R. H. LOCK (*London: J. Murray, 1906, pp. XV+299, pls. 5, figs. 47*).—In this volume an attempt is made to summarize some of the results of recent investigations bearing upon the subject of heredity for the purpose of indicating, wherever possible, their value to the breeder of animals and plants. Especial attention is given to natural selection, biometry, mutation, Mendelism, and cytology. Examples chosen to illustrate various features of evolution and heredity are drawn both from the plant and animal kingdoms and from the work of recent and also some of the older investigators.

Mammals of the Mexican boundary of the United States, E. A. MEARNS (*U. S. Nat. Mus. Bul.* 56, pt. 1, pp. XV+530, pls. 13, figs. 126).—The biological section attached to the international boundary survey between Mexico and the United States made observations on the mammals and plants of that region. A list is given of the trees observed along the Mexican boundary line together with a general account of the botanical features of this region and the flora. The greater part of the volume (pp. 149-501) is occupied with a detailed discussion of the mammals of the region belonging to the orders Marsupialia, Edentata, Ungulata, and Glires. Particular attention is devoted to the ground squirrels and mice.

Useful birds and their protection, E. H. FORBUSH (*Boston: Mass. Bd. Agr., 1907, pp. XX+437, pls. 56, figs. 171*).—The Massachusetts State Board of Agriculture, in recognition of the economic importance of birds in the control of insect pests, provided an appropriation for the preparation of a volume covering the general habits of birds and their protection. The subject matter is largely based on the facts and conditions observed in Massachusetts, but also applies in large part to other sections of the country.

The subjects discussed in the volume include the general value of birds to man; their utility in orchards, woodlands, fields, and gardens, the natural checks which operate to diminish the multiplication of birds, and practical methods for the protection of all useful birds.

An ornithological cross-section of Illinois in autumn, S. A. FORBES (*Bul. Ill. State Lab. Nat. Hist.*, 7 (1907), Art. 9, pp. 305-335).—The purpose of the observations reported in this article was to determine the relative frequency of different species of birds, the feeding habits of which are fairly well known. For this purpose two of the assistants of the author were instructed to travel across the State of Illinois from east to west, noting the species and number of individuals of birds which could be observed within a strip of land 150 ft. wide extending across the State. The area covered by these observations was 3,519 acres, and the total number of birds identified was 4,804, of which 1,620 were English sparrows and 3,184 native species. The observations showed the presence of 874 birds per square mile, or 1.36 per acre.

A number of tables are presented, showing the relative frequency of the 18 most important native birds of Illinois, the number of birds observed in fields of different crops, and the apparent preference of birds for certain crops. It

is believed that after more field work of this sort has been done a reliable basis will be formed for generalizations regarding the actual value of birds to the farmer.

A history of the commission of agricultural parasitology, A. MERAZ (*Bol. Com. Par. Agr.*, 4 (1907), No. 1, pp. 106, pls. 3).—The results obtained by the Mexican commission of agricultural parasitology during the past 6 years are summarized in this report with particular reference to the bearing of this work upon the advancement of practical agriculture. Particular mention is made of the work of the commission in the study of injurious insects and fungus diseases.

Entomological notes, W. W. FROGGATT (*Agr. Gaz. N. S. Wales*, 18 (1907), No. 2, pp. 149-152).—Brief notes are given on the bot fly, the elephant beetle on apple trees, and wireworms in pastures.

Report upon the work of the State crop pest commission, W. NEWELL (*Crop Pest Com. La. Circ.* 13, pp. 11).—Brief mention is made of the details of office work, publication of circulars, exhibits at fairs, cooperation with the Bureau of Entomology of this Department, and lectures given by the members of the Louisiana Crop Pest Commission. Attention is being given to nursery inspection, the eradication of the white fly and cattle ticks, and a study of the New Orleans ant. In 1906, the red-pink fungus was introduced into Louisiana orange groves, and despite the dry season which is considered unfavorable to its development, more than 95 per cent of the white flies were destroyed by it.

Insects and diseases liable to be introduced into Mississippi, G. W. HERICK (*Mississippi Sta. Bul.* 96, pp. 16, figs. 9).—Attention is called to the possibility of introducing into Mississippi the San José scale, new peach scale, woolly aphis, strawberry louse, cotton-boll weevil, black knot, crown gall, and peach rosette. These pests and fungus diseases are briefly described and directions are given for combating them if they should appear.

A natural history of the British lepidoptera, J. W. TUTT (*London: Swan, Sonnenschein & Co.; Berlin: Friedländer & Son*, 1906, vol. 5, pp. XIII+558, pls. 6).—In the first part of this volume a general account is given of hybrids and mongrels among lepidoptera with numerous instances of each and with mention of the laws of heredity observed in these phenomena.

The greater part of the volume is occupied with a detailed account of the group Alucitides, including descriptions of species, analytical tables for identification of species, and biological notes.

The principal animal enemies of wheat, L. VIVARELLI (*Rivista*, 4, ser., 13 (1907), Nos. 1, pp. 5-9; 2, pp. 33-37; 3, pp. 56-60; 4, pp. 80-84; 5, pp. 105-108; 6, pp. 129-131; 7, pp. 158-161; 8, pp. 172-174, figs. 3).—The author presents a general review of the known facts regarding the appearance, biology, and means of combating the more important insect and other enemies of wheat. In this discussion notes are given on cockchafers, wireworms, mole crickets, cutworms, Hessian fly, wheat midge, *Sitophilus granarius*, grain weevil, nematode worms, and certain species of birds.

Thrips, L. P. DE BUSSY (*Médec. Deli-Proefstat. Medan*, 1 (1907), No. 5, pp. 172-174).—A brief report is made of the injury to tobacco as a result of a serious infestation with tobacco thrips. In combating this pest the best results were obtained from the thorough application of kerosene emulsion.

Economic notes on aphids and coccinellids, R. H. JOHNSON (*Ent. News*, 18 (1907), No. 5, pp. 171-174).—In studying lady beetles the author has had occasion to observe plant lice on various native and introduced species of plants, some of which are not commonly reported as being infested with plant lice. It appears that the lady birds which feed upon these plant lice are not found in the same abundance on all of the host plants upon which the plant lice feed.

The apple woolly aphis and remedial measures. Green apple leaf aphis and remedies, R. I. SMITH (*Ga. Bd. Ent. Bul.* 23, pp. 48, figs. 10).—A comparison of various remedies for the woolly aphis showed that kerosene emulsion used at a strength of 15 per cent is most effective. In applying this remedy the soil should be removed to a depth of $2\frac{1}{2}$ to 3 in. around the trunks of trees and the kerosene emulsion applied directly to the soil. For small trees the area thus treated may be 3 ft. in diameter, and for this from $2\frac{1}{2}$ to 3 gal. of kerosene emulsion would be required. For larger trees with roots spreading 3 or 4 ft. in all directions, soil should be removed from a circle of not less than 4 ft. in diameter and from 5 to 6 gal. of emulsion applied. In the case of trees from 4 to 10 years of age this treatment will cost from 4 to 8 cts. per tree. One application is sufficient for a year, and two applications in successive years will practically destroy the woolly aphis.

Less satisfactory results were obtained from the use of tobacco dust, tobacco stems, carbon bisulphid, and whale-oil soap.

The apple leaf aphis may be successfully controlled by spraying with a tobacco decoction prepared by boiling 3 lbs. of tobacco stems in 5 gal. of water for 2 hours or by spraying with a 20 per cent kerosene emulsion.

Results obtained by Berlèse and Silvestri in combating the olive fly, CUBONI (*Bol. Quind. Soc. Agr. Ital.*, 12 (1907), No. 7, pp. 226-231).—The injuries caused by the olive fly have been successfully combated by the use of a mixture containing 65 parts molasses, 31 of honey, 2 of glycerin, and 2 of arsenate of soda. Before using, this stock mixture is diluted with 10 parts of water.

Fruit fly, J. S. JEFFERSON (*Jour. Dept. Agr. West. Aust.*, 15 (1907), No. 3, pp. 161-166).—In combating this pest it is necessary promptly to remove and destroy infested fruit in order to prevent the great multiplication of the fly. Brief notes are given on the distribution of the fly in Western Australia and the probable means by which it is accomplished.

The fruit-tree leaf-roller, J. M. STEDMAN (*Missouri Sta. Bul.* 71, pp. 21, figs. 14).—*Cacaccia argyrosphila* fortunately does not occur every year in large numbers. In some cases the damage is excessive to all kinds of orchard trees.

In the experiments carried out by the author it was found that the insect has but one brood annually, that the winter is passed in the egg stage on twigs and small branches, and that the larvæ appear in May and feed upon the young leaves and buds. These larvæ are partly protected by the leaves which they fasten about them, but the thorough application of arsenate of lead just before the blossoms open or just after they have fallen and before the larvæ have completed their leaf nest gives satisfactory results.

The gipsy moth in Maine, E. F. HITCHINGS (*Bul. Maine Dept. Agr.*, 6 (1907), No. 1, pp. 18, pls. 2, figs. 5).—A brief historical account is given of the gipsy moth in the United States, and particularly in Maine, together with notes on the habits and life history of the insect. The present status of the moth in Maine is indicated, and a copy is given of the recent State law for the protection of trees and shrubs and of the rules adopted by the commissioner of agriculture in carrying out this law.

Spiders and the nun moth, C. LOOS (*Centbl. Gesam. Forstw.*, 33 (1907), No. 3, pp. 109-115, fig. 1).—Observations were made on the effectiveness of spiders in the destruction of the nun moth in its various stages.

Phylloxera in Vatellina, G. MOLOX (*Agr. Mod.*, 13 (1907), No. 11, pp. 156-159, figs. 4).—The present status of the phylloxera in this region is briefly described with notes on the methods which have been undertaken for its control.

Three enemies of the cacao in Saint Thomas, M. MONTEP (*Jour. Agr. Trop.*, 7 (1907), No. 70, pp. 106-109).—In the author's opinion the 3 worst enemies of cacao in Saint Thomas are rats, white ants, and an unidentified insect borer.

Rats may be controlled to some extent by the use of infectious virus and poisoned baits and by the mongoose. The nests of white ants are quite easily destroyed by the use of bisulphid of carbon.

Insects in the coniferous forests of Vosges in 1906, DE GAIL (*Rev. Eaux et Forêts*, 46 (1907), No. 6, pp. 161-164).—A careful survey of this region was made to determine the extent of infestation of coniferous trees with various species of bark beetles and weevils. The results are stated in a tabular form. It is believed that in such work frequent reconnaissances are desirable. Trees found to be infested should be immediately cut and the bark removed.

A homemade and effective insect trap, J. D. EVANS (*Canad. Ent.*, 39 (1907), No. 5, pp. 150-152, fig. 1).—The author has had excellent success in catching insects for collections from the use of a simple trap. This consists of a paper funnel in which an incandescent light is suspended and which opens below into a glass jar containing cyanid of potash.

A new method of preparing arsenate of lead, L. DEGRULLY (*Prog. Agr. et Vit. (Ed. l'Est)*, 28 (1907), No. 16, pp. 462, 463).—On account of his inability to obtain acetate of lead upon the market, the author used nitrate of lead for the preparation of arsenate of lead by combination with arsenate of soda. For this purpose, good results were obtained when 0.5 kg. arsenate of soda in 5 liters of water was added to 1.2 kg. nitrate of lead in 5 liters of water.

Annual report of the Bee-Keepers' Association of the Province of Ontario, 1906 (*Ann. Rpt. Bee-Keepers' Assoc. Ontario, 1906*, pp. 64).—In this report a record is given of the proceedings of the twenty-seventh annual convention of the Ontario Bee-Keepers' Association held in Toronto, November 7-9, 1906. The discussions at the various sessions were largely of a practical nature and concerned chiefly the production and marketing of honey. The essential points in the production of comb honey were discussed by U. H. Bowen (pp. 14-16). The matter of inspection for foul brood received considerable attention, and a copy is given of the Ontario Act for the suppression of this disease.

Short accounts were also presented of beekeeping as an occupation for women, apiary appliances, retailing honey, fall management of bees, etc.

The classification, biology, and distribution of the honeybee, H. von BUTTELREEPEN (*Mitt. Zool. Mus. Berlin*, 3 (1906), No. 2, pp. 117-201, figs. 8).—The present monograph on the honeybee includes a discussion of the original home of the honeybee and its relatives, the instincts of bees, the systematic relationship of the honeybee and other species, and an elaborate account of the biology of bees. The literature of the subject is discussed in connection with a bibliography of 140 titles. Analytical tables are presented for the identification of varieties of bees related to the honeybee, and descriptions are given of the common races of the honeybee and other species of bees known to be of possible value for the collection of honey.

Rearing queens, E. GIRAUD (*Apiculteur*, 51 (1907), No. 4, pp. 157-163, figs. 4).—A description is given of the form and characters of the natural cell in which queens are reared, and attention is called to the importance of rearing queens at home in order to be sure of the breeding and to save expense. The author describes and illustrates practical methods by which queen cells may be started and the worker bees induced to supply these cells with royal jelly for the development of the queens.

Amount of water necessary for bees, G. GENDOT (*Apiculteur*, 51 (1907), No. 4, pp. 164-168).—Statistical data are presented relating to the quantity of water required by bees under various conditions. According to the observation of the author and other investigators, it appears that bees need from $\frac{1}{2}$ to $\frac{3}{4}$ kg. of water daily per colony. It is desirable, therefore, that attention be given to

this point so that the bees may have an adequate supply of pure water conveniently located.

Disinfection of silkworm nurseries by means of a new method, GASPERINI (*Bol. Quind. Soc. Agr. Ital.*, 12 (1907), No. 7, pp. 292-294).—In outbreaks of flaccidity among silkworms, the author obtained excellent results in controlling the disease by fumigating with a mixture of nitrate of potash and sulphur, allowing the fumes to operate for 24 hours.

FOODS—HUMAN NUTRITION.

Twenty-first annual report of the Ohio dairy and food commissioner, II. ANKENY (*Ann. Rpt. Ohio Dairy and Food Comr.*, 21 (1906), pp. 98).—The work of the State dairy and food commission with reference to the examination of foods and drugs, the legal prosecutions resulting from the work, the financial report for the year, and several special reports are included in this publication, as well as a summary of the State food laws. Of the 1,964 samples examined, 834 were found to be adulterated. As a result of the work prosecutions were brought during the year on 121 articles.

An examination of canned chicken, veal loaf, and similar goods showed that the greater number of these samples had to be classed as adulterated. "The chicken and turkey samples were chiefly other meats. Some of the samples contained tin and zinc, which was evidently due to the poor quality of the containers or lack of care in canning. A few contained either boric, benzoic, or salicylic acid, while perhaps half contained sulphites reported by chemist as traces only or as added sulphites."

Corn oil; its possible use as an adulterant in lard and its detection, W. McPherson and W. A. Ruth (pp. 18-23).—Maize oil, or corn oil, a by-product in the manufacture of starch and glucose, was the subject of special investigation, as the material is attracting attention as a food stuff and is rumored to be used as an adulterant for culinary fats. To determine the effects of the presence of corn oil in lard, 3 samples of pure lard were mixed with definite quantities of the oil and tested for making different sorts of pastry, etc., under the auspices of the domestic science department of the Ohio State University. Judged by quality and appearance, the presence of corn oil did not appreciably affect the quality and palatability of the food in which it was used. "No physiological tests were carried out, but considering the source of the oil and its similarity to wholesome vegetable oils, there can be little doubt as to its food value. Whether corn oil is actually used as an adulterant of lard or not, the above results show that lard containing as high as 10 per cent of the oil might easily pass for the pure product."

The chemical and physical characteristics of lard, corn oil, and mixtures of the two were studied with a view to finding a satisfactory method for detecting the presence of corn oil, but neither the iodine number, the butyro-refractometer readings, nor color tests gave satisfactory results. The best results were obtained by separating the unsaponifiable product according to Bömer's acetate method. "The percentage of sitosterol in corn oil is much larger than the percentage of cholesterol in lard, and this fact, together with the fact that the melting points of the acetyl derivatives of the cholesterol and sitosterol are so far apart (113° and 127°-128°, respectively), renders it possible to detect even very small amounts of corn oil present in lard."

"It is a noteworthy fact that the melting point of the acetyl derivative obtained from the lard containing even 2 per cent of corn oil is markedly higher than the corresponding derivative obtained from pure lard. This would indicate that in the process of purification the sitosterol is obtained nearly pure."

The method outlined "would, of course, fail in the presence of cotton-seed oil. It is doubtful, however, whether the latter oil is used to any extent as an adulterant of lard at present, due undoubtedly to the ease with which it can be detected. In the examination of a large number of commercial samples of lard made during the last three years in this laboratory not a single sample was found adulterated with cotton-seed oil.

"The large amount of ether necessary for the extraction of the unsaponifiable products . . . renders it an expensive . . . [method] to carry out. The ether, however, may be largely recovered by distillation. An investigation is now being carried out in this laboratory with the hope of so modifying the method as to overcome the above objection."

Sulphurous acid in meats, O. S. MARCKWORTH (pp. 29-39, dgms. 2).—Methods for determining the presence of sulphurous acid in meat were studied with samples of pork and beef with special reference to the determination of the amount of sulphur which may be normally present as a result of decomposition.

"For the recovery of sulphurous acid in meats, at least, iodine should not be used as an absorbent when it is to be determined volumetrically or gravimetrically. The results are most erratic and unreliable. On the other hand bromine water is efficient and reliable. There does not seem to be much ground for the assertion that too much sulphurous acid is indicated by the use of bromine as an oxidant. The quantities found in fresh, uncontaminated samples of both pork and beef are so small as to be negligible when calculated to SO_2 . (This may not apply to meats long refrigerated or canned.)

"The amount of volatile sulphur compounds will probably furnish a check on the age of meats, whether fresh, refrigerated, or canned.

"The cause of the [observed] difference in the amount of SO_2 recovered from pork and beef must be left for continued study. It is no doubt partially explained by the difference in the amount of fat in the respective samples.

"It is my opinion that fresh meats should be condemned when showing more than 0.0025 per cent sulphur calculated to SO_2 for when showing this amount they have already become more or less disintegrated by bacteriological action. Any amount above 0.0025 per cent must either be attributed to excessive age or added sulphites."

The pure food and drug laws of the State of Indiana (Indianapolis: Ind. Bd. Health, 1907, pp. 64).—Provisions of the State laws which have to do with foods and drugs are given and an index is provided. The regulations regarding sanitary conditions take into account the health of employees in dairies, bakeries, etc., and the condition of abattoirs and slaughterhouses, groceries and meat markets, drug stores, hotels, and restaurants.

Report of committee on adulterations of foods, seeds, and other products, and legislative enactment recommended, S. B. PACKARD, H. R. WRIGHT, and C. F. CURTISS (*Des Moines: Iowa Dept. Agr., 1906, pp. 41*).—Data regarding the composition of concentrated feeds and condimental feeds have been noted from publications of the Iowa Experiment Station (E. S. R., 18, p. 966).

Proteids in the peanut seed, M. SOAVE (*Ann. R. Accad. Agr. Torino, 48 (1905), p. 1; abs. in Zentbl. Physiol., 20 (1906), No. 23, p. 773*).—A proteid with diastatic properties was isolated, as well as two proteids soluble respectively in sodium-chloride solution and a dilute alkaline solution. These soluble proteids on hydrolysis yielded different amounts of histidine and arginine, and so may be regarded as different bodies. No alcohol soluble proteid resembling zein was found.

Oil-bearing seeds (Transvaal Agr. Jour., 5 (1907), No. 18, pp. 411, 412).—A note reporting analyses of "Marula" nuts and "Maraamas" beans. The latter plant is not identified botanically.

Concerning a little-known edible mushroom, A. R. CHIAPPELLA (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 13 (1907), No. 7, pp. 384-389).—Descriptive and analytical data regarding an edible mushroom (*Boletus bellini*) are reported and discussed.

The identification of schi fruit and illipe fruit and their products, E. SCHAFFNIT (*Landw. Vers. Stat.*, 65 (1907), No. 5-6, pp. 449-456, pl. 1).—The manufacture of culinary fats from the fruits of *Butyrospermum parkii* and illipe species is described. The residue from fat extraction is used to some extent as a feeding stuff and as an adulterant for concentrated feeds. The microscopic structure of these materials is described with a view to their identification.

Concerning the ash content of paprika, R. WINDISCH (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 13 (1907), No. 7, pp. 389-397).—The results of studies of the ash content of a number of sorts of paprika are discussed with reference to the use of such data for the detection of adulteration. According to the author, an ash content of 7 to 8 per cent is not proof that paprika is adulterated, provided a careful study of other characteristics or constituents indicate that it may be pure.

Concerning edible earths, BALLAND (*Jour. Pharm. et Chim.*, 6, ser., 23 (1906), pp. 181-183; *abs. in Ztschr. Untersuch. Nahr. u. Genussmtl.*, 13 (1907), No. 7, p. 433).—As analyses show, so-called edible earths contain no nutritive material.

Lead and arsenic in tartaric acid, citric acid, and cream of tartar, A. W. J. MACFADDEN (*Local Govt. Bd. [Gt. Brit.], Med. Dept., Rpts. Insp. Foods, 1907, No. 2, pp. 10*).—With a view to obtaining data for standards of purity a large number of samples of tartaric acid and cream of tartar were examined. Small quantities of lead were found in nearly every sample and very small quantities or traces of arsenic in a number of samples, these metals being accidental impurities.

“Lead and arsenic are two substances in which the deleterious effect of continued ingestion of small doses has been clearly shown. It should be the aim of the manufacturer to exclude both these substances from articles of food and food ingredients. Looking to all the circumstances, however, and having in view the quantities in which tartaric and citric acids and cream of tartar are consumed in food, drinks, medicines, etc., it is reasonable to conclude that minute amounts of lead or arsenic (arsenious oxid) below 0.002 per cent and 0.00014 per cent, respectively, would not be sufficient to justify their condemnation.”

Concerning the water content of cooked sausage, H. LÜHRIG and A. SARTORI (*Pharm. Centralhalle*, 48 (1907), No. 14, pp. 265-268).—The data here given include determinations of the water content of small sausages known as Vienna sausage or Frankfort sausage, before and after smoking, after the short cooking in hot water which the sausage receives at the factory and after the further cooking to which they are usually submitted before they are eaten. The work was undertaken with a view to securing data for use in the prevention of an undue water content when sold.

The preservation of eggs by water glass and the composition of the preserved eggs, J. HENDRICK (*Jour. Agr. Sci.*, 2 (1907), No. 1, pp. 100-105).—The examination of a large number of eggs preserved in trade lots in large tubs showed that a few were bad or unsalable. For instance, out of 384 dozen eggs examined 5 dozen, or 1.3 per cent, were bad, the great majority being broken or cracked eggs. The eggs preserved in water glass were usually of good quality and could hardly be distinguished in appearance, flavor, and smell, either raw or cooked, from so-called fresh eggs—that is, eggs a few days old. As the

period of preservation increases a distinct change is noted both by the eye and palate. Eggs which have been 3 or 4 years in water glass are easily recognized, the white becoming pink in color and very limpid. "The slight alteration in the flavor of the egg and in the liquidness of the white may be due to the increase in soda." Even when 4 years old no unpleasant taste or smell was observed and the white coagulated in the usual manner when cooked. There was a slight characteristic odor which did not suggest sulphureted hydrogen. "The changes in the preserved eggs take place very gradually. At 1 year old they are hardly noticeable; at 2 years they are distinct, but not so distinct as at 3 or 4 years old."

To summarize the data gained from general observations a number of experiments were made in which fresh eggs and eggs preserved for different lengths of time were compared, the principal results being as follows:

Composition of fresh and preserved eggs.

Kind of egg.	Water.	Nitro- gen.	Fat.	Ash.	Potash.	Soda.	Silica.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Fresh eggs.....	73.18	2.11	10.40	1.02	0.120	0.194	0.010
Eggs preserved 1 year.....	73.55	2.01	10.70	.93	.101	.215	.022
Eggs preserved 2 years.....	73.73	2.07	10.41	1.02	.073	.311	.039
Eggs preserved 2 years.....	72.12	2.17	11.19	0.92	.075	.296	.023
Eggs preserved 3 years.....	74.66	2.10	9.42	1.00	.069	.343	.019

In general, "there is practically no change in the composition of eggs even from lengthened immersion in water glass. Practically no silica and very little, if any, soda find their way into the eggs."

To determine whether much silica was deposited in the shells of preserved eggs the shell and adhering membrane of a number of samples were analyzed. "If we omit the different quantities of organic matter adhering to the shells, the main difference between the different samples is in the amount of silica which they contain. In the fresh eggs this is about 0.5 per cent, and it increases according to the length of time the eggs have been in the solution. In the eggs which were 3 years in the solution the silica amounts to nearly 2.5 per cent. It appears, then, that a slow deposition of silica takes place in the shell of the egg. The percentage of lime in the shells remains practically constant. This deposition of silica in the shells probably blocks up the pores of the shells to some extent and renders them less permeable."

Analyses of the sodium silicate used for the preservation of eggs showed that it "does not contain quite sufficient soda to form the acid metasilicate, NaHSiO_3 . The solution given by the water glass is strongly alkaline in reaction."

A sample of sirup-thick water glass contained 37.91 per cent silica, 16.48 per cent soda, and 0.14 per cent potash, and a solution prepared for preserving eggs 2.76 per cent silica, 1.20 per cent soda, and 0.01 per cent potash.

Influence of temperature and atmospheric moisture on the preservation of eggs, DE LOVERDO (*Compt. Rend. Acad. Sci. [Paris], 144 (1907), pp. 41-43*).—Fresh eggs, it was found, could be preserved for months in the cold without loss in weight or any apparent change, provided the temperature was kept at -1°C . and the moisture content of the air at 78° . If the temperature is lower than -1.5°C . the eggs freeze, while if the air is more moist they will mold.

Chemical composition of oyster liquor, J. BAYLAC (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 6, pp. 259-252*).—Analyses of the liquor of oysters from the Mediterranean and from the ocean, which are reported in full, showed that the composition of the liquor of each variety is relatively constant as regards

albumin (about 2 gm. per liter being present), urea, ammonium salts, phosphates, sulphates, chlorids, potassium, silica, etc. The Mediterranean oyster liquor contained a larger quantity of organic material than that of oysters from the ocean.

Experiments on the metabolism of matter and energy in the human body, 1903-1904, F. G. BENEDICT and R. D. MILNER (*U. S. Dept. Agr., Office Exptl. Stat. Bul.* 175, pp. 335, pls. 2, figs. 7).—Like the experiments reported in earlier bulletins (*E. S. R.*, 15, p. 608) those here described furnish important data regarding the transformations of matter and energy in the body, the demands of the body for nutriment, the effect of muscular work upon such demands, and the actual nutritive values of the different kinds of food materials and their ingredients. These experiments differ materially from those previously reported, however, in that the respiration calorimeter with which they were made has undergone an important modification which permits the direct measurement of the amount of oxygen consumed by the subject, thus affording a more complete balance of income and outgo of matter and energy than has ever been possible hitherto.

The account of the experiments is preceded by a description of the respiration calorimeter in its present form. As modified, the apparatus is of the closed-circuit type, the respiratory products (carbon dioxide and water vapor) being removed and fresh oxygen supplied to the continuous ventilating air current.

Among the questions discussed on the basis of experimental data are the digestibility of food, the metabolism of nitrogen and protein, the elimination of carbon dioxide and water, heat production, bodily activity and the measurement of muscular work, fats versus carbohydrates as protectors of protein, protein as a source of energy for muscular work, the relative efficiency of fats and carbohydrates in rations for muscular work, the conservation of energy in the body, and problems of ventilation.

As regards the theory that protein is the source of muscular work the results of the investigations reported indicate that with all due allowance for any delay in the excretion of nitrogen resulting from the katabolism of protein induced by severe muscular work, the total probable disintegration is still far from sufficient to supply all the energy for external muscular work.

As regards the relative efficiency of fats and carbohydrates in rations for muscular work the results, in the authors' opinion, "seem to warrant the belief that fats are possibly slightly inferior to carbohydrates as sources of energy for muscular work."

The following deductions the authors consider justified from the data supplied regarding ventilation: "An increase in the amount of carbon dioxide present in the air is absolutely without effect on the mental and bodily comfort of the subjects of the experiments. These subjective observations are paralleled by observations on the respiratory exchange and heat output, neither of which factors is in any way affected. The so-called concomitant impurities of the earlier writers were not discovered in this research. The subjects at no time complained of headache or other discomfort. It is conceivable, to be sure, that the impurities from one individual would have no deleterious effect upon the same individual, but might have on another; yet the water condensed from the respired air, which would probably contain large proportions of such impurities if there had been any, when injected into white rats showed no indication whatever of any virulent toxic poison; and . . . [it seems probable] that the unusual control of thermometric and hygrometric conditions of this form of respiration calorimeter precludes conditions of temperature and humidity ordinarily present in poorly ventilated rooms."

The functions of food in the body, A. RABAGLIAT (*London: Elliot Stock, 1907, pp. 46; rev. in Brit. Med. Jour., 1907, No. 2419, p. 1125*).—In this discussion of body dynamics the author advances the theory that the body secures its energy during sleep, though he admits that the ultimate source of vital energy is not known. In his opinion, energy is not derived from food and he believes that man eats too much.

A graphic method in practical dietetics, I. FISHER (*Jour. Amer. Med. Assoc., 48 (1907), No. 16, pp. 1316-1325, figs. 15*).—The data reported in this description of a method and apparatus for determining food values have been noted from another publication (*E. S. R., 17, p. 1174*).

Biological energetics. The greater expenditure of energy pertaining to a meat diet in comparison with the expenditure which occurs when food materials containing all 3 nutrients are consumed, A. CHAVEAU (*Compt. Rend. Acad. Sci. [Paris], 144 (1907), No. 4, pp. 173-178, fig. 1*).—Experiments were made with dogs at rest and performing a known amount of work to determine the relations existing between the nature of the nutrients and the activity of the respiratory exchanges taken as an indication of the expenditure of energy occurring in connection with their assimilation. There were experiments with no food as a basis of comparison and others with a uniform basal quantity of meat supplemented by equivalent quantities of sugar, fat, and meat.

According to the author, the results of both the rest and the work experiments agree in showing that the utilization of the nutrients by the organism, that is, their digestion, absorption, and assimilation, entails an increased consumption of oxygen, indicative of an increase in the energy expenditure of the organism, the increase being slight in the case of the carbohydrates, somewhat greater in the case of fat, and very decidedly larger in the case of the proteids. The author states that there is no indication that this extra energy metabolism is due to increased internal activity of the organism and he believes that the cause, whatever it may be, is not in accord with the principle of isodynamism.

Concerning the rapidity of protein cleavage in the animal body, W. FALTA (*Deut. Arch. Klin. Med., 36 (1906), pp. 517-564; abs. in Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 2 (1907), No. 1, p. 29*).—According to the author's observations, the cleavage of large quantities of pure proteids in the body does not progress as rapidly as has been supposed, 3 or 4 days being required for the excretion of all the nitrogen derived from even those which are easily broken down. The rapidity of cleavage differs with various proteids, and the proteids studied may be arranged according to this property in the following groups: (1) Gelatin, casein, serum albumin and fibrin, (2) blood globin, (3) hemoglobin, and (4) ovovitellin and genuine ovalbumin. Nitrogen retention and similar questions are discussed.

Concerning the digestibility of fat in the animal body, S. LEVITES (*Ztschr. Physiol. Chem., 49 (1906), No. 2-3, pp. 273-285*).—Experiments on the digestibility of butter fat, beef suet, and lard led to the following conclusions:

The digestibility of fat involves two chemical processes, namely, the cleavage of the fat into fatty acids and glycerin and the formation of salts of the fatty acids. Neither of these processes is carried on to completion since the condition of equilibrium is always reached between neutral fat and fatty acids or neutral fat and fatty acids and their salts. In the stomach fat undergoes only a little chemical change (saponification) so long as the liquid from the duodenum does not pass into the stomach. When this takes place the fat cleavage is considerable. Fat is not resorbed in the stomach. Resorption takes place first in the upper part of the small intestine, either in the form of free fat or free fatty acid, but further investigations are needed before the form in which fat is resorbed can be stated.

A parallelism may be noted between fat cleavage (saponification) and fat resorption, and the greater the cleavage the greater the resorption. Fat without the addition of other food stuffs is well assimilated by the body, the proportion resorbed being about 96 per cent in the case of butter and beef fat. Lard is somewhat less thoroughly assimilated, probably owing to its laxative properties.

The experiments reported were made with dogs having operative fistulae.

The effect of training upon the muscular power with isometric work, A. F. HELLSTEN (*Skand. Arch. Physiol.*, 19 (1907), No. 1-3, pp. 218-230).—From investigations with young men in training for a boat race, the author concludes that in order to obtain the maximum effort from a muscle or group of muscles the power of coordination must be developed. The relation of this power to fatigue and related matters are spoken of. Fatigue manifests itself more slowly with trained than with untrained muscles.

ANIMAL PRODUCTION.

Feeding stuff inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul.*, 142, pp. 93-114).—The feeding stuffs examined under the provisions of the State law included cotton-seed meal, cotton-seed feed, linseed meal, gluten feed and meal, distillers' grains, brewers' grains, alfalfa meal, proprietary feeds, molasses and sugar feeds, corn and oat feeds, oat feeds, hominy feeds, miscellaneous starchy feeds, wheat offals, and beef scraps. Most of the feeding stuffs met, or very nearly met, their guarantee.

"The cotton-seed meal situation has been a very unfortunate one in Maine the present year. In the late fall the cotton crop was very seriously damaged by a storm which resulted in a smaller yield of cotton seed than was anticipated, and also made considerable dark-colored meal. This shortage materially advanced the price of choice cotton-seed meal and increased the quantity of meal that was below prime in quality."

Many feeding stuffs composed of refuse from milling oats, corn, etc., are on the market. "For the most part these goods are fairly well up to their guarantee and no fault can be found with the manufacturer for desiring to sell these waste products. Few or no claims are made for nutrients which the goods do not actually carry."

Though many of the corn and oat feeds meet their guarantee this was not the case with some of the corn and oat feeds and mixed feeds. "There is no class of feeding stuffs in which the consumer needs to use greater care at present than in the purchase of mixed feeds. While the regular brands are all right, as they have been in the past, there are some spurious articles in the market." Apparently fraud was intended with only one brand of wheat offals.

As regards beef scraps it was pointed out that the guarantee placed on the goods is in some instances at least only a very general guide to their actual composition.

Stall feeding versus grazing, A. M. SOULE and J. R. FAIN (*Virginia Sta. Bul.*, 164, pp. 51-88, figs. 11).—Tests were made to compare the cost and possible profits of fattening cattle in stalls with feeding a low grain ration through the winter in stalls and finishing on grass.

In the test with stall-fed cattle, which covered 180 days, 6 lots of 8 steers each were used. It was also a part of the plan to study the comparative value of different corn products when fed with cotton-seed meal and so the grain ration, which averaged 6.7 lbs. per head per day at the beginning of the test, was made up of ear corn, split corn, fine corn-and-cob meal, and coarse corn-and-cob meal each with cotton-seed meal 1:1, and shelled corn and corn meal each with cotton-seed meal about 2:3. The coarse fodder in every case consisted of corn silage, hay, and corn stover. As the test progressed the amount of grain and

the proportion of corn were increased, but the grain never exceeded 12.5 lbs. per head per day.

The gains ranged from 1.29 lbs. per head per day on the split corn and cotton-seed meal ration to 1.74 lbs. on corn meal with cotton-seed meal. Considering the average values the gain on the whole corn rations was 1.42 lbs. per head per day and on the corn meal of different sorts 1.52 lbs. As regards the feed eaten per pound of gain the highest values 7.46 lbs. grain and 20.02 lbs. coarse fodder, were noted with the split corn ration and the lowest values, 5.52 lbs. grain and 15.23 lbs. coarse fodder, with the corn meal ration.

Pigs followed each lot of cattle fed a ration containing whole corn, the number per lot being 2 at the beginning and 4 at the close of the test. The best gain, 0.78 lb. per head per day, was made on shelled corn and the smallest gain 0.6 lb., by the animals following steers fed split corn.

“Though 3.25 lbs. of cotton-seed meal were fed per head per day during the entire feeding period of 180 days, in only one instance did the hogs following show any evidence of ill health. Of the 12 hogs following the cattle, 1 died suddenly, but the cause could not be determined.

“The hogs following the groups receiving whole corn made 937 lbs. of pork, which, at 5 cts., was worth \$46.85 or \$1.95 per steer. This gave the groups receiving whole corn a material advantage over those fed ground corn.

“These results indicate that cattle can not be fed in the stall under a margin of 75 cts. where they are charged the full market price for all the foodstuffs fed. On the basis of the actual cost of the foodstuffs on the farm, they could often be fed on a margin of 50 cts. and still give the farmer a fair profit on his operations.”

The possible profits from feeding cattle in stalls are discussed on the basis of different margins, and in the authors' judgment it would be comparatively easy under good management to feed beef cattle on a margin of 1 per cent profit on the basis of the gains and food cost indicated in this report. Where larger gains are obtained and the food is secured at a lower cost the profits would be correspondingly greater.

In the second test 4 lots of 9 steers each were fed in stalls for 161 days a low grain ration, 2 lbs. per head per day, made up of corn-and-cob meal and cotton-seed meal 1:1, and supplemented respectively by hay, corn stover, corn silage, and a mixture of the silage and stover 1:1, and then pastured for 138 days, the range being at the rate of 5 acres per steer.

While in stalls the average gain per head per day varied from 0.12 lb. with the stover-fed lot to 0.85 lb. on silage. On pasture the smallest gain, 1.67 lbs. per head per day, was noted with the lot which had been fed a mixture of silage and stover and the greatest gain, 2.2 lbs., with the hay-fed lot. Considering the test as a whole, the smallest gain, 1.05 lbs., was noted with the stover lot and the greatest gain, 1.26 lbs., with the silage lot. The gain was least expensive, when the whole test was considered, with the silage-fed lot, costing 4.12 cts., and greatest with the hay-fed lot, being 6.64 cts. per pound, values which are about half of those noted with the stall-fed cattle in the first test.

A special object of the investigation was to compare silage and stover, and a slaughter test showed that the average dressed weight of the silage-fed cattle was 57.07 per cent and that of the stover-fed cattle 56.3 per cent of the live weight. Though the percentage difference was small the extra amount of beef produced on the silage ration, according to the authors' calculation, was 316 lbs., which, at 8 cts. per pound, would make \$25.28, or about 25 cts. per 100 lbs. live weight, in favor of the silage ration.

“From the results it appears that the cattle receiving silage as their sole roughness during the winter made the largest average gains, did not drift

materially when turned on grass after the first 10 days, slaughtered out to better advantage than the dry-fed cattle, and were in a thriftier and better condition throughout the entire feeding period. This is sufficient proof of the fact that succulent foods can be fed to cattle maintained as stockers and finished on grass. . . .

"Cattle can be handled advantageously as stockers and finished on grass on a margin of 25 cts. where silage or stover or other inexpensive forms of roughness are used during the winter. Mixed hay proved so expensive that there was a loss with it on a margin of 50 cts.

"The cost of a pound of gain with the stall-fed cattle varied from 7.33 to 9.01 cts.; with the stocker cattle from 4.12 to 6.64 cts. It cost . . . nearly twice as much to make a pound of gain in the stall as where the animals were finished on grass. . . .

"The beef made per acre by the grazers varied from 46 to 60 lbs., or a return of from \$2.12 to \$2.82 per acre. An acre in silage yielding 8 tons will provide roughness for 4 animals for 180 days, which shows the importance of the silo where intensive farming is practiced, and the fact that larger returns can be secured from the land through the medium of the silo than were obtained through grazing in these experiments. . . .

"The deductions to be drawn from the experiments with feeders are as follows: Feed a small grain ration—not over 2 lbs. per head per day to commence with, and increase it gradually until the cattle are ultimately consuming 15 lbs. per head per day. A liberal ration of silage should be fed throughout the test, decreasing the amount consumed toward the close of the feeding period. Only a minimum amount, not over 2 to 4 lbs., of stover or other dry inexpensive forms of roughness need be fed.

"It would appear that silage may constitute the chief source of roughness for stockers; that a grain ration of 2 lbs. per head per day is sufficient to insure their making substantial and profitable gains during the winter; that the best results will be obtained when the ration consists of equal parts of corn-and-cob meal and cotton-seed meal or some other food rich in protein.

"The feeding value of silage is in a large measure due to its comparative richness in nutrients especially suited for the nourishment of cattle, its ease of digestion as compared with dry foods, its palatability due to its aroma and succulence, and the fact that it aids in cooling the system and keeping it free of effete material and keeping the circulation active."

Baby beef, E. G. RITZMANN (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1905, pp. 181-212, pls. 2, figs. 3; Circ. 105, pp. 34, figs. 6*).—The feeding, care, and management of cattle to produce early maturity—i. e., baby beef—are discussed as well as the present condition of the industry in the United States and similar topics.

"Baby beef is a special article in which the essential characteristics are early maturity, quality, finish, and thickness of flesh. Nine out of ten yearlings sent to market for slaughter do not class as baby beef, because they lack finish or quality, while some are overfed or 'overdone.' This results from lack of a proper understanding of the qualities that constitute the condition known as ripeness or 'finish.' . . .

"Maturity for the block in beef cattle means that condition when they have reached full growth of body and are thoroughly fat or ripe for slaughter. The average age at which cattle are now fully grown and fattened for the market is between 2 and 3 years. Early maturity, therefore, means that the animal has been fully grown and fattened in less than the average length of time required by that class of stock. . . .

"When early maturity is attempted by means of liberal feeding with nutritious

feed, carbonaceous in character and lacking in bulk, the tendency to produce flesh and fat is readily developed; but owing to the smaller proportion of nitrogenous constituents contained in such feed and its lack of bulk the animal's frame does not make a proportionate development, and its natural growth is checked at the expense of the development of flesh and fat. Consequently a slight reduction in size and greater fineness of bone are generally associated with early maturity.

"When very heavy feeding is resorted to there is always the danger of over-feeding, which often results in permanent injury to the animal."

Before weaning, whole milk is the best feed for calves, though good results may be obtained with skim milk if the whole milk is not available.

"Calves fed on skim milk tend to grow in frame rather than to fatten, although their gains may be as rapid as the gains made by calves fed on whole milk. The use of skim milk in producing baby beef therefore lengthens the period of production. . . .

"The method of feeding adopted [after weaning] . . . will depend largely upon the nature of the feeds available and the season of the year. Previous to weaning the ration consists of whole milk supplemented by grain, or skim milk with a small amount of flaxseed jelly, or some other substitute to take the place of butter fat in addition to grain. Corn with milk produces an excellent balance of heat, fat, and muscle-producing feed. After weaning the protein of the milk must be restored by some other feed, although a relatively smaller proportion of it becomes necessary as the calf grows older.

"In the summer time the best combination to furnish the proper balance is a good pasture (bluegrass is preferred for pasture, because it is firm and contains a large percentage of nutrients) and shelled corn or a little oats, if they are cheap enough. Occasionally a little cotton-seed meal, gluten meal, linseed meal, or bran may help to balance the ration and tend to stimulate the appetite. . . .

"Some of the most successful feeders of baby beef have used silage (from 15 to 25 lbs. daily) with good results in a ration consisting of about 3 lbs. corn meal, 2 lbs. wheat bran, and plenty of clover hay. In such a ration the silage will add the succulence, but if silage is not available a small quantity of roots will answer the same purpose. . . .

"Of all the fodders good clover and alfalfa hay have no equal, as they will supply the protein or muscle-making properties that must otherwise be supplied in the form of nitrogenous commercial products, which generally prove very expensive. If the roughness consists largely of such feeds as corn fodder, oat hay, timothy hay, or prairie hay, then some nitrogenous concentrate should be added to give the proper balance.

"Under present conditions the market does not discriminate between steers and heifers for baby beef, as the latter sell for equally high prices as the steers, provided they are equally well finished.

"Some of the principal advantages derived from the production of baby beef as compared with older beef are (1) the quick returns on the investment, (2) the greater demand for the product, and (3) the greater amount of meat produced per pound of feed consumed.

"In feeding baby beef the profit comes in within two years after birth of the calf. In case, also, of the loss of an animal this would be considerably smaller in a young animal, because the latter represents a smaller bulk and has, moreover, been produced at less cost per pound of live weight. On the other hand, the lighter the animals are marketed the more breeding stock is necessary to produce an equal amount of marketable beef. The extra cost of keeping this additional number of breeding stock, however, is offset by doing away with the

cost of keeping steers the third year; thus the number of marketable stock kept on the farm is increased."

Welsh black cattle, J. ROBERTS (*U. S. Dept. Agr., Bur. Anim. Indus, Rpt. 1905, pp. 161-180, pls. 5; Circ. 10, pp. 29, pls. 5*).—The Welsh breed of cattle is considered to be very valuable in Great Britain. The cows are good milkers but the breed is chiefly famous for its feeding qualities and the admitted excellence of the carcass. The author has summarized data regarding the origin and history, characteristics, feeding and management of Welsh cattle, prices of pedigreed stock, and similar topics.

"Welsh cattle are sometimes criticized on the score of late maturity. They probably were somewhat slow feeders in the past, but the adherents of the improved breed claim it is now in the front rank of rapid fatteners. . . .

"The Welsh is not one of the so-called 'fashionable' breeds; consequently pure-bred animals of good quality can generally be bought for much less than the prices paid for well-bred specimens of such breeds as the Shorthorn, Hereford, or Aberdeen-Angus."

Sheep feeding, F. W. WILSON (*Arizona Sta. Rpt. 1906, pp. 152, 153*).—Alfalfa and barley hay, alone, mixed, and supplemented by oat hay were compared with 4 lots of 10 sheep each.

In the 38 days of the test there was a loss of 2.5 lbs. per lot on the barley hay ration, and gains of 27.5 lbs. on alfalfa and barley hay, 35 lbs. on alfalfa, barley hay, and oat hay, and 140 lbs. on alfalfa hay alone. In the case of the last mentioned lots, the feed eaten per pound of gain ranged from 6.96 lbs. on alfalfa hay alone to 27.09 lbs. on alfalfa and barley hay. The greatest range in cost of a pound of gain was also noted with these lots, being 3.1 cts. and 12.2 cts., respectively.

"Alfalfa hay seems to be more palatable to sheep than barley hay or oat hay. This was clearly shown in the lots receiving alfalfa as a part of the ration. The sheep picked out a greater portion of the alfalfa and ate it before eating the balance of the ration.

"Oat hay seems more palatable to them than barley hay. The beards from barley roll up between the teeth and the jaw, causing irritation. The lots receiving barley as a part of the ration were troubled a great deal and had to have the beards removed."

The results are in accord with those reported with steers in an earlier publication of the station (*E. S. R., 17, p. 278*).

Sheep breeding, F. W. WILSON (*Arizona Sta. Rpt. 1906, pp. 153-155*).—Brief statements are made regarding the progress of breeding tests using native ewes and a Tunis buck.

Sweet clover in San Luis Valley, C. A. LYMAN (*Breeder's Gaz., 51 (1907), No. 17, p. 961*).—Sweet clover, according to the author, when young and tender, is an excellent pasture plant for pigs. It should be cut when 6 in. high, as if allowed to grow older it becomes tough and bitter, so that stock will not eat it.

Government encouragement of imported breeds of horses, G. M. ROMMEL (*U. S. Dept. Agr., Bur. Anim. Indus, Rpt. 1905, pp. 147-159*).—The effect of the present tariff and similar topics are discussed with special reference to the acknowledged needs of the establishment of breeds of horses in this country, particularly draft horses.

"The complete withdrawal of the duty-free privilege, without the present restrictions regarding pedigree and registration, would be undesirable, for the reason that short-bred animals recorded in European books of record would not be kept out. As it is at present, the importer does not bring in such

animals, the duty preventing him, although he could do so if he wished by paying the duty and thus avoiding the scrutiny of his pedigree certificates.

"A more reasonable plan, which has much of merit, is that a duty be placed on males, the importation of females of approved pedigree being permitted without duty. This would give a very desirable impetus to the importation of mares. If this plan were adopted, it would seem desirable to require the importer to state whether his animals were intended for breeding purposes and to have the present pedigree restrictions apply to breeding males as well as females."

Poultry management, G. A. BELL (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1905, pp. 213-266, pls. 5, figs. 7*).—A summary and discussion of data on poultry feeding, including such topics as the classification of fowls, the selection of varieties, houses, and inclosures, the equipment of poultry houses, the management of hens for egg production, raising chickens, broilers, roasters, and capons, fattening poultry, feeding, care, and management under different conditions, marketing poultry and poultry products, preserving eggs, and the diseases of poultry.

Capons and caponizing, R. R. SLOCUM (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1905, pp. 267-275, pl. 1, figs. 6; Circ. 107, pp. 10, figs. 8*).—The selection of breeds, time for caponizing, instruments used, methods of operating, care after the operation, feeding capons, killing and dressing for market, and similar topics are discussed in this general summary of data on the subject.

Cold storage poultry fallacies exploded, H. A. HIGLEY (*Food Law Bul., 2 (1907), Nos. 1, pp. 6-8; 2, pp. 21-23*).—The author differs from the majority who have studied the question with reference to the effects of storing poultry undrawn, and, in addition to discussing the reports of previous investigations on this subject, briefly states the results of his own investigations. His conclusion follows:

"All bacteriological evidence conclusively proves that the edible portions of healthy, dead, undrawn poultry and game do not contain any bacteria, toxins, or ptomaines that are harmful when eaten by man so long as such poultry is kept free from putrefaction. . . . Poultry that goes into cold storage in good bacterial condition comes out in exactly the same condition that it went in, so long as the temperature of the poultry is kept low enough to prevent the growth of putrefactive bacteria, and finally that the longer poultry remains frozen the less bacteria does it contain."

Annual production of animals for food and per capita consumption of meat in the United States, J. ROBERTS (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1905, pp. 277-290*).—A summary and discussion of statistical data.

According to the author's calculations the total per capita consumption of meat in the United States for the year 1900 was 178.75 lbs., beef contributing 78.71 lbs., veal 3.35 lbs., pork, including ham and bacon, 88.12 lbs., and mutton and lamb 8.57 lbs. For purposes of comparison data regarding the estimated per capita consumption of meat in other countries are summarized.

Market prices of live stock (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1905, pp. 286-290*).—Tables are given which show the prices of various classes of live stock at Chicago and Omaha during the year 1905.

The movement of live stock (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1905, pp. 291-293*).—Data regarding the receipts and shipments of live stock and other topics concerning the commercial movement of live stock are summarized.

Registered live stock in the United States December 31, 1905 (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1905, pp. 294-297*).—Statistical data are summarized.

DAIRY FARMING—DAIRYING.

Investigations on the influence of proteids upon milk production and on the relation between starch value and milk yield, A. MORGEN, C. BEGER, and F. WESTHAUSSER (*Landw. Vers. Stat.*, 66 (1907), No. 1-2, pp. 63-165).—In experiments with 10 sheep and 1 goat the authors studied the effects of increasing the daily allowance of digestible protein from 3 kg. to 9 kg. in rations containing different amounts of fat.

The results showed that an increase in the amount of protein was followed in most instances by an increase in the yield of milk and milk constituents. The percentages of fat and total solids in the milk, however, were decreased. The increase in the yield of milk due to the feeding of more protein was most marked when the fat content of the ration was 1 kg. per 1,000 kg. live weight. The decrease in the fat content of the milk was more marked when the fat in the ration was low than when it was normal or high. A large amount of fat in the ration increased apparently the yield and fat content of the milk.

Rations having the same starch value exerted the same influence upon milk production only when the amounts of protein and fat necessary for a maximum production were present.

The effect of feeding cows rations rich and poor in proteids, A. SCHMECK (*Illus. Landw. Ztg.*, 27 (1907), No. 41, pp. 373-375).—In experiments with 2 cows a comparison was made of rations containing 2.25, 1.58, 1.21, 0.83, and 0.50 kg. of digestible protein per 1,000 kg. live weight. The corresponding nutritive ratios were 1:6, 1:9, 1:12, 1:18, and 1:30. When less than 1.21 kg. of digestible protein was fed daily there was a decided loss in live weight. The ration richest in protein was the most favorable for milk production.

Influence of feeding beet leaves and tops upon the composition of butter fat, M. SIEGFELD (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 13 (1907), No. 9, pp. 513-524).—During the feeding of beet leaves and tops to about 40 cows for over 2 months the Reichert-Meissl, Polenske, and saponification numbers were high and the iodine number and the average molecular weight of the nonvolatile fatty acids were low.

Influence of feeding on the composition of butter fat, C. AMBERGER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 13 (1907), No. 10, pp. 614-621).—In experiments with 2 cows, feeding a ration rich in sugar was without influence on the properties of the butter fat. A ration richer in protein than that ordinarily fed, however, decreased the Reichert-Meissl number from 25.48 to 16.70, the Polenske number from 1.8 to 1.6, and the saponification number from 225.5 to 219.5, and increased the iodine number from 32.1 to 39.2.

The dairy cow, J. S. MOORE (*Mississippi Sta. Bul.* 95, pp. 23, figs. 5).—This bulletin deals in a popular manner with the principal dairy breeds, the selection of cows, the keeping of dairy records, testing milk, dairy feeds, feeding standards, calculating rations, pastures, soiling crops, care of cows, raising calves, and other topics. The difference in individual cows is illustrated by the average records of 2 cows for 3 years. One produced 5,003 lbs. of milk and 294 lbs. of butter at a cost for feed of \$34.20 a year, and the other produced 5,725 lbs. of milk and 428 lbs. of butter at a yearly cost for feed of \$30.44. A table is given showing the dry matter and digestible nutrients in feeding stuffs. Ten suitable rations for dairy cows are included.

Records of dairy cows: Their value and importance in economic milk production, C. B. LANE (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt.* 1905, pp. 111-146, pls. 7, figs. 6; *Circ.* 103, pp. 38, figs. 10).—Largely an abstract of Bulletin 75 of the Bureau previously noted (*E. S. R.*, 17, p. 693).

The composition of milk. H. D. RICHMOND (*Analyst*, 32 (1907), No. 374, pp. 141-144).—The average composition of 13,513 samples of milk received from farms and examined during 1906 was as follows: Specific gravity 1.0322, total solids 12.64 per cent, and fat 3.71 per cent. The average fat content of the morning's milk was 3.55 per cent and of the evening's milk 3.88 per cent.

Contribution to the knowledge of milk, E. FYNX (*Centbl. Bakt. [etc.]*, 2. *Abt.*, 18 (1907), No. 13-15, pp. 428-439, pls. 2).—Samples of whole milk and milk diluted to different degrees with water were sterilized by heating at 105° C. on 3 consecutive days. The author observed after 1 week certain microscopic changes in the samples which were attributed to peptonization, and which were more marked the greater the dilution. The samples were studied microscopically in hanging-drop preparations made by diluting a drop of the milk with water and staining by the addition of borax-methylene blue. The many changes observed in the fat globules are described in detail and fully illustrated.

The author also describes the cellular elements observed in both human and cow's milk and the changes taking place in them when mixed with sterile bouillon and kept in the incubator for several days. In sterile bouillon to which a few drops of blood were added similar transformed cellular elements were observed. The observations, however, are insufficient to warrant definite conclusions as to whether or not certain cellular elements in milk are derived from the blood. Sterile milk when added to bouillon seemed to exert a slight bactericidal action toward the typhoid bacilli.

Nature and value of goat's milk, A. BURR (*Mitch Ztg.*, 36 (1907), Nos. 19, pp. 219, 220; 20, pp. 229, 230; 21, pp. 241, 242).—This is a compilation of information relating to the composition and utilization of goat's milk.

The acid coagulation of milk, C. REVIS and A. PAYNE (*Jour. Hyg. [Cambridge]*, 7 (1907), No. 2, pp. 216-231).—Experiments were undertaken to secure information on the increase in acidity of milk in relation to the development of lactic-acid bacteria. The results failed to throw light on the cause of the delay in acid formation in comparison with the increase in bacteria, but are considered by the authors as elucidating some of the chemical changes which take place progressively as milk sours. They suggest, however, as highly probable that the bacteria develop the power of producing acid only after a certain period of growth.

The experiments show that the lactic acid first produced is not neutralized by some of the constituents of the milk. The amount of lactic acid combined with the casein as well as the amount of calcium triphosphate combined with the casein were found to be directly proportional to the total lactic acid present. The authors conclude that the compounds of calcium salts and of lactic acid with casein as they are formed in milk do not possess the definite compositions of the compounds formed by calcium and lactic acid with casein after its separation from milk as described by Söldner and by Van Slyke and Hart.

The presence of a kinase in cow's milk, A. HOUARDY (*Acad. Roy. Belg., Bul. Cl. Sci.*, 1906, No. 12, pp. 888-900).—The digestion of milk by the pancreatic juice is retarded by heating the milk for 20 minutes at 75° C. or above and hastened by the addition of enterokinase. The author found that a cube of coagulated egg albumen was more readily digested by the pancreatic juice when previously macerated in milk. This increased digestibility was, however, nullified by heating the sensitized cube for a half hour at 73°.

The conclusion is therefore drawn that there is present in milk a substance capable of increasing the activity of the pancreatic juice in the same manner as the enterokinase of Pawlow. The name lactokinase is proposed for this hitherto undescribed substance.

Leucocyte standards and the leucocyte content of milks from apparently healthy cows, H. L. RUSSELL and C. HOFFMANN (*Jour. Infect. Diseases*, 1907, No. 3, Sup., pp. 63-75).—The authors have compared the Doane-Buckley and Stokes-Stewart methods of determining leucocytes in milk and have studied the leucocyte content of the milk of the cows of the University of Wisconsin dairy herd from June to October.

Of the two methods compared the Doane-Buckley method is considered more accurate, equally rapid, and less trying on the eyes.

The herd was divided into 2 groups. Group 1 contained 18 cows in perfect health, and group 2 contained 12 cows having udder indurations of varying severity, but with one exception producing apparently normal milk. Of the 537 tests made of the first group, 31.1 per cent fell below 50,000 per cubic centimeter, 19.8 per cent were between 50,000 and 100,000, 39.4 per cent between 100,000 and 500,000, 6.8 per cent between 500,000 and 1,000,000, and 2.9 per cent above 1,000,000. The corresponding percentages for the 371 tests made of the second group were 13.2, 16.4, 45.9, 12.4, and 12.1.

The leucocyte content of the milk of apparently normal animals was often in excess of the standards which have been proposed, indicating, according to the authors, that complete reliance can not be placed upon quantitative standards alone.

The relative importance of streptococci and leucocytes in milk, N. M. HARRIS (*Jour. Infect. Diseases*, 1907, No. 3, Sup., pp. 50-62).—The author concludes that there is at present no reliable method for distinguishing pathogenic from nonpathogenic streptococci in milk, and that the sanitary significance of both streptococci and leucocytes or pus cells in milk has been overrated. He believes that more attention should be given to veterinary inspection of the cow's udder and less dependence placed upon laboratory examination of milk for signs of infectious processes.

The comparative value of bacterial and temperature regulations for a city's milk supply, F. H. SLACK (*Jour. Infect. Diseases*, 1907, No. 3, Sup., pp. 76-81).—Since May, 1904, the regulations of Boston have required that the market milk of that city shall not contain more than 500,000 bacteria per cubic centimeter nor have a temperature above 50° F. The article gives the results of plate counts and temperature determinations of 11,403 samples taken during this period.

The results show that 66 per cent of the samples were within both standards, 11.25 per cent had high temperatures and low bacterial contents, 17.5 per cent had high bacterial contents and low temperatures, and 5.25 per cent were outside both standards.

Of the two tests the bacterial count is considered much the more important.

The bacteriological characteristics of different types of milk fermentations, M. DÜGGELE (*Centbl. Bakt. [etc.]*, 2. Abt., 18 (1907), Nos. 1-3, pp. 37-49; 7-9, pp. 224-245; 13-15, pp. 439-448, *abm.* 1).—This article gives the bacteriological characteristics of the different groups of lactic-acid bacteria.

Soft-cheese studies in Europe, C. THOM (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt.* 1905, pp. 79-109, pls. 3).—The author visited cheese factories and markets in England, France, Italy, and Germany, paying particular attention to the groups of cheese in which molds are the principal ripening agents.

Mold-ripened cheeses are divided into two groups, the Brie-Camembert group and the Gorgonzola-Roquefort-Stilton group. Rather detailed notes are given on the manufacture of each of these varieties. Of the first group the Brie and Camembert are considered the only varieties worthy of consideration. It is believed that these two types of cheese may be made with success anywhere if the necessary conditions are observed and proper ripening agents introduced.

VETERINARY MEDICINE.

Feeding stuffs and infection, L. PICOLLO (*Bol. Agr. [São Paulo]*, 8. ser., 1907, No. 1, pp. 20-27).—The susceptibility of the alimentary tract to infection with anthrax, tuberculosis, and other diseases is briefly discussed with notes on the economic importance of giving attention to the sanitary condition of feeding stuffs.

A new yeast pathogenic to man and animals, F. STEINHAUS (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 43 (1906), No. 1, pp. 46-69).—*Saccharomyces membranogenes* was first obtained from the throat in a case of scarlet fever. Experiments with this organism showed that it was pathogenic for mice, guinea pigs, and rabbits, and that the infection thus produced was severe in all cases. As a rule the eruption of miliary tubercles in all organs appeared in the inoculated animals.

Metabolic products in rabbits inoculated with fatal doses of hog cholera and anthrax bacilli, E. LEVY and L. BECKMANN (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 43 (1906), No. 1, pp. 43-48).—A careful study was made of a normal serum of rabbits as compared with that obtained after inoculating these animals with fatal doses of hog cholera or anthrax bacilli. In these experiments, the conclusion was reached that no toxic metabolic products are formed in the rabbit during the course of these diseases, or at least that no such products pass over into the blood serum.

Rabies as related to rats and mice, C. FERMI (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 43 (1907), Nos. 2, pp. 173-178; 3, pp. 218-222).—In the experiments reported in this paper it was found that nearly all of the inoculated rats and mice developed a fatal form of rabies. In these experiments fixed virus was used. A virus of unusual virulence was obtained and tested on 49 birds belonging to a number of genera. None of these animals became infected.

With regard to the possible distribution of rabies by rats and mice some cases are on record in which the disease was apparently transmitted by the bites of these animals, but the dog is considered to be the main agent. Mice and rats are readily infected by feeding upon rabies virus, a result which is quite contrary to that obtained in experiments with dogs.

The maximum dilution of rabies virus for the production of an infection with this disease, C. FERMI (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 43 (1907), No. 5, pp. 446-448).—By the use of a fixed virus it is found possible to inoculate mice hypodermically using a dilution of 1:50,000. Rats and mice appear to be more susceptible to greatly diluted hypodermic injections than are dogs.

Contagious diseases of animals in foreign countries (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1905*, pp. 298-305).—A statistical summary is given of infectious diseases reported during 1905 in Europe.

The diseases of animals and meat inspection in Western Australia, J. B. CLELAND (*Jour. Dept. Agr. West. Aust.*, 15 (1907), No. 2, pp. 84-94).—Particular attention is given to a discussion of infectious diseases which are communicable to man and to other diseases which are of most importance in meat inspection. The pathological conditions referred to by the author include tuberculosis, actinomycosis, hydatids, pleuro-pneumonia, Texas fever, bladder worms, tumors, melanotic conditions, and fatty necrosis.

Tables are given showing the prevalence of the various diseases in animals as determined in the course of meat inspection.

Division of animal industry, V. A. NÖRGAARD (*Rpt. Bd. Comrs. Agr. and Forestry Hawaii*, 3 (1906), pp. 165-205, pls. 3).—A record is given of the correspondence regarding animal quarantine in Hawaii during the year under report.

Some trouble has been experienced in combating glanders in Hawaii on account of the failure of horse owners in the Islands to understand the action and value of mallein. It is believed that glanders prevails to a large extent throughout the Territory.

Brief notes are also given on osteomalacia, osteoporosis, embolic colic in horses and mules, redwater in cattle, sheep scab, epizootic lymphangitis, and various diseases of dogs.

Precipitin reaction as a means of distinguishing between tubercle bacilli of human and bovine origin, A. BONOME (*Centbl. Bakt. [etc.]*, 1. *Abt.*, *Orig.*, 43 (1907), No. 4, pp. 391-407).—The author's experiments and observations on the phenomenon of the precipitation of tubercle bacilli with immune sera showed that the blood sera of animals or man affected with spontaneous cases of tuberculosis have a precipitating power toward proteids from fresh tuberculous tissue or toward proteid substances extracted from cultures of tubercle bacilli. Occasionally normal serum has this power to a limited extent. The precipitating power of the blood serum in a case of tuberculosis does not act in the same manner toward material obtained from different animals which are spontaneously affected with tuberculosis. Thus immune serum of tuberculous human patients was found to be particularly active toward tubercle bacilli and tuberculous material obtained from human beings.

By means of this biological method of precipitation it is possible to distinguish sharply between human and bovine tubercle bacilli.

The action of formaldehyde upon the tubercle bacillus and *Staphylococcus pyogenes aureus*, G. MARTINOTTI (*Centbl. Bakt. [etc.]*, 1. *Abt.*, *Orig.*, 43 (1907), No. 3, pp. 246-257).—Tubercle bacilli, cultivated in agar and subjected to the action of formaldehyde fumes, show a considerably greater resistance to these fumes than does *Staphylococcus pyogenes aureus*. It was found possible, however, not only to delay the development of tubercle bacilli by means of formaldehyde, but to destroy them entirely.

The effect of toxins upon tuberculous subjects in tuberculous products sterilized by heat, V. GALTIER (*Jour. Méd. Vét. et Zootech.*, 58 (1907), Mar., pp. 129-132).—The author considers it as demonstrated beyond question that sterilized tuberculous products are not pathogenic and that the toxin contained in them is not injurious to healthy animals or human beings. Experiments with tuberculous dogs indicate clearly that the toxin contained in sterilized tuberculous meat and other organs exercises no unfavorable effect upon the progress of the tubercular infection.

Modes of tubercular infection in wild animals in captivity, W. R. BLAIR (*Amer. Vet. Rev.*, 30 (1907), No. 11, pp. 1299-1306, figs. 2).—The author has had an extensive experience with diseases in captive animals in zoological parks and gives special attention in this article to an account of tuberculosis in such animals. It appears that in most cases of tuberculosis in monkeys and other captive animals, the disease was contracted before the animal reached the zoological park, probably while in the unsanitary quarters of dealers or in unclean cars and transport vessels. The general character of tuberculous lesions found in monkeys agrees closely with those in human beings and the infection usually appears first in the cervical and bronchial lymph nodes.

Tuberculosis in chickens positively identified in New York, S. H. BURNETT (*Amer. Vet. Rev.*, 30 (1907), No. 11, pp. 1312-1314, figs. 4).—A short account is given of an outbreak of tuberculosis in a flock of poultry together with notes on the pathological lesions observed. It appears from the study of this outbreak that tuberculosis must be quite generally distributed in poultry, but it was impossible to trace the source of infection.

The influence of mammalian and avian tubercle bacilli on the reaction of the culture medium, O. BANG (*Centbl. Bakt. [etc.], 1. Abt., Orig., 43 (1906), No. 1, pp. 34-43, figs. 2*).—As the result of a long series of cultures with tubercle bacilli of different origin it was found that with regard to its reaction on culture media, the avian tubercle bacillus behaves very much like the bovine form. It appears, however, to render the culture medium somewhat more decidedly alkaline. The reaction produced by the human tubercle bacillus may be somewhat changed by altering the supply of oxygen, but the change thus induced is not great enough to bring about a confusion between the bovine and human tubercle bacillus.

Anthrax and imported animal products, W. HANNA (*Pub. Health [London], 19 (1907), No. 7, pp. 439-459*).—On account of the interest which attaches to the means by which anthrax is spread, particularly through commerce in hair and hides, the author examined into the records of 21 human cases of anthrax in Liverpool.

The study of these cases indicates clearly that all workmen should be warned by proper circulars against the possibility of infection with anthrax, and that all foreign hides from suspected countries should be scheduled under special rules and should be imported only in large canvas-covered bales, requiring mechanical handling. It is recommended that the hides be shipped wet rather than dry and that infected material be traced to its source of origin and an attempt made through official channels to secure veterinary inspection in the locality where the disease originated.

The persistence of the Texas fever organism in the blood of southern cattle, E. C. SCHROEDER and W. E. COTTON (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1905, pp. 71-78*).—Three southern cows were used to test the persistence of the blood parasite of Texas fever. The cows were protected from exposure to the disease during the experiments. It was found that the blood parasite persisted for 10 to 12 years. Apparently excessive infestation with cattle ticks may so reduce the resistance of cattle to Texas fever that an acute form of the disease may develop in cattle which were apparently immune and showed blood parasites in an inactive condition.

Notes on the cattle tick and Texas fever, E. C. SCHROEDER (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1905, pp. 49-70*).—A résumé is given of the life history of the cattle tick. The average time required for a full life cycle is 54 days, and the average length of time for the deposition of the eggs is 7 days. It was determined that adult ticks may be kept without material injury for at least 96 days at temperatures below freezing.

The average incubation period for tick eggs is 25 days, the shortest observed period being 12 days, and the longest 209 days. This time depends largely on the temperature. The eggs may be exposed for several weeks to temperatures below the freezing point without destroying their vitality. On an average, cattle ticks mature in 22 days, the shortest period being 15 days, and the longest 40 days.

Considerable attention was given to a study of the influence of cattle ticks upon cattle aside from being agents in the transmission of Texas fever. In the growth of the cattle tick its weight increases about 10,000 times during the 3 weeks. This constitutes a serious drain upon the vitality of infested cattle, some of which are killed outright. Calves become badly stunted as a result of infestation. Pathological changes were noted in the skin about the point where the ticks were attached. The actual weight of ticks which mature and fall off may amount to $\frac{1}{2}$ oz. to several ounces daily. It was shown that cattle on which from 100 to 150 ticks were daily matured showed in some instances a diminution

in the red blood corpuscles to the extent of 7 or 8 per cent. The exact cause of this destruction of the blood corpuscles was not determined.

A general review is given of the cattle tick as a disseminator of Texas fever. In exterminating cattle ticks it is necessary to consider the maximum and minimum periods required for the tick to pass through its various stages. According to the author's experiments, ticks may live at least 322 days without any host.

An outbreak of rinderpest in the Philippine Islands, R. H. McMULLEN (*Amer. Vet. Rev.*, 30 (1906), No. 9, pp. 1063, 1064).—A description is given of an outbreak of rinderpest on the Island of Luzon which was traced to a shipment of 150 head of cattle from the Island of Mindoro. Infection spread quite rapidly throughout a territory containing 20,000 cattle and caribao, and in some localities the mortality was 90 per cent. The further spread of the disease was completely checked by the preventive inoculation of all exposed animals.

Influence of milk of different degrees of acidity on the health of calves, A. PIROCCO (*Clin. Vet. [Milan]*, 30 (1907), No. 2, pp. 59-82, fig. 1).—Careful feeding experiments were carried out on 8 calves, during which milk of a varying degree of acidity was used. In these experiments it was found that milk with a slight acidity, as it comes from cows on a mixed or succulent ration, exercises a more or less laxative effect upon calves. Feeding experiments with milk just on the point of turning sour showed that such milk may be very harmful to calves a week old or less, producing, in some instances, serious gastro-intestinal disturbances.

The action of the ether extract of antitetanus serum, P. CERNOVODEANU and V. HENRI (*Compt. Rend. Soc. Biol. [Paris]*, 62 (1907), No. 9, p. 392).—In experiments in vitro it was found that the ether extract of antitetanus serum possesses striking antihemolytic power in neutralizing the tetanus toxin. Thus, when the ether extract of the serum was diluted a thousand times with a sodium chlorid solution at the rate of 8 parts in 1,000, this solution was capable of completely neutralizing the hemolytic action of 1 cc. of tetanus toxin.

Measurement of anaerobiosis of tetanus bacillus, G. ROSENTHAL (*Compt. Rend. Soc. Biol. [Paris]*, 62 (1907), No. 10, pp. 438-440).—In the author's experience if an aerobic culture of the tetanus bacillus be sown in deep tubes of milk with a pipette, the tubes containing whole milk will show a rapid growth whatever the height of the tubes, while in tubes containing skimmed milk, positive results are obtained after 48 hours to a depth of 9 to 10 cm. In tubes filled with bouillon or peptonized glycerin, an abundant growth of the bacillus was observed after several days to a depth of 15 to 18 cm.

Thrush in horses, P. LAHILLE (*Bol. Min. Agr. [Buenos Ayres]*; 6 (1906), No. 5, pp. 251-261, figs. 9).—In one locality alfalfa was excessively infested with *Aphis medicaginis*, and since horses fed upon the alfalfa showed symptoms of thrush about the eyes and on the other parts of the skin, it was suspected that the aphid might be the cause of the trouble. An examination of the alfalfa showed that in addition to *A. medicaginis* a number of red spiders were present, particularly *Tetranychus silvestrii*. It is believed that this mite was the cause of the trouble observed in horses.

Hemorrhagic hepatitis in antitoxin horses, P. A. LEWIS (*Jour. Med. Research*, 15 (1906), No. 3, pp. 449-468, pl. 1).—The sudden occurrence of a large number of deaths among horses used for the production of diphtheria antitoxin led to the study of the cause of this trouble. It was found not to be due to any alteration in the blood corpuscles, but to the amyloid degeneration of the liver which develops in a certain percentage of cases as the result of frequent bleedings for the purpose of obtaining serum. Horses suffering with amyloid degeneration

of the liver are subject to hemorrhage and rupture of the organ, allowing the blood to flow freely into the body cavity.

The Sarcosporidia of sheep, F. JANIN (*Arch. Par.*, 11 (1907), No. 2, pp. 233-268, pl. 1, figs. 3).—An elaborate biological account is given of the peculiar protozoan organisms known as Miescher's sacs and by other names and frequently observed as parasites of domestic animals, including sheep. A study of these organisms has convinced the author that the 2 genera *Sarcocystis* and *Balbiania* should be retained and that *B. gigantea*, found about the esophagus of sheep, is identical with *Sarcocystis tenella*. Notes are given on the biology of these parasites and on the various forms observed in their development.

Structure of the spore of *Sarcocystis tenella* in sheep and goats, L. PERRIER (*Compt. Rend. Soc. Biol. [Paris]*, 62 (1907), No. 10, pp. 478-480).—The spore of this micro-organism, belonging to the Sarcosporidia, is described in detail and attention is called to the bearing of these facts upon the relationship between Sarcosporidia and Myxosporidia.

A spirillosis and a hematozoal disease of domestic fowls in the Anglo-Egyptian Soudan, A. BALFOUR (*Brit. Med. Jour.*, 1907, No. 2413, pp. 744, 745).—The author observed a spirillosis of fowls apparently identical with a form of septicemia described from outbreaks in Brazil and elsewhere. In the outbreak referred to by the author the birds had been imported from Italy and it is suggested that an infection may have taken place through the agency of ticks on shipboard. The incubation period is believed to be 5 or 6 days.

A piroplasmosis was also observed and the author suggests that this disease may be carried by ticks of the genus *Argas*.

The biology of the organism of fowl plague, A. LODE (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 43 (1907), No. 4, pp. 355-359).—The literature relating to the pathogenic organism of fowl plague is briefly discussed with notes on the results which the author obtained in his experiments. Pieces of infected tissue placed in glycerin remain infectious for at least 3 to 4 months. The resisting power of the virus of fowl plague in a 50 per cent glycerin suspension was almost equal to that of *Staphylococcus pyogenes aureus*. In general, the resisting power of the virus toward all kinds of antiseptic agencies is greater than that of ordinary bacteria and in the author's opinion raises the question whether *Spirillum parvum* should be considered as belonging to the bacteria.

RURAL ENGINEERING.

Report on irrigation and drainage investigations during 1905-6, W. W. McLAUGHLIN (*Utah Sta. Bul.* 99, pp. 126, pls. 2, figs. 8).—In the bulletin are included reports upon the various irrigation and drainage investigations carried on by the Utah Station in cooperation with this Office during the years 1905-6.

The irrigation investigations were carried on in Sevier, Tooele, Boxelder, Utah, Millard, Salt Lake, Weber, Morgan, and Cache counties, in each of which attempts were made to determine the proper amounts of water to use in irrigation and the proper number of applications. While various untoward circumstances somewhat impair the reliability of the results, two hypotheses were evolved which further experiments are needed to verify, viz. that "crop production tends to vary as the amount of water applied within certain limits," and "that the productive value of an inch of irrigation water depends upon the amount of water which has already been applied during the season."

The drainage investigations were confined to those portions of the State where land had become boggy or alkaline through seepage of water from adjacent and higher irrigated fields. Experimental drains were installed on various farms in six counties of the State and the results carefully noted in each instance. The

data accumulated have a more particular value to the respective localities than to any others, but the experience so far derived indicates that check gates are necessary at various points in the drains, which may be closed when irrigation water is applied and opened later for drainage. Otherwise soil is washed into the drains, it being evident from the experiments that more care was necessary in the irrigation of under-drained than ordinary fields.

Some suggestions are also made as to needed amendments in the existing drainage law.

Making the most of a small water supply, R. H. FORBES (*Arizona Sta. Bul. 54*, pp. 103-111, figs. 2).—The author describes a system of water distribution especially adapted for orchards and vineyards, in which a pipe leads from the reservoir or pump along the lines of trees or shrubs, a small hole being bored in the pipe opposite each plant.

Some experiments were made upon the flow of water from such small orifices, from which in connection with practical considerations it was decided that the smallest orifices, or those of $\frac{3}{8}$ in. in diameter, gave the best results. The pipe is laid slightly below the surface and each orifice discharges into a shallow basin surrounding the tree or shrub. This basin is mulched over with manure or chip dirt which greatly lessens evaporation. The irrigation plant described by the author consists of a well with water at a depth of 90 ft., a 3 by 14 in. pump cylinder operated by a 12-ft. geared windmill, a 5,000-gal. tank, and distribution lines of $\frac{3}{4}$ -in. pipe. This irrigates, even in a region of light winds, 87 useful trees and 32 vines and bushes, besides furnishing the domestic supply for a house, thus showing the possible use which can be made of a very small water supply.

Weirs for irrigating streams, G. E. P. SMITH (*Arizona Sta. Bul. 54*, pp. 111-117, fig. 1).—The author describes the Cipolletti weir, giving the conditions which must be observed in its construction and including a table of discharges for a weir 1 ft. in width.

Determination of stream flow during the frozen season, H. K. BARROWS and R. E. HORTON (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 187*, pp. 93, pl. 1, figs. 14).—In this paper the authors discuss the modifications of the usual methods of stream measurements which are necessary to secure good results when the streams are ice covered. The conditions affecting the formation of ice and its effect on stream flow are considered in some detail particularly with reference to the formation of the ice sheet and the variation in slope due to freezing.

The methods of obtaining winter records of stream flow are described, these consisting usually of readings of gage heights and current-meter discharge measurements. The reading of gage heights is taken to the water surface as shown in a hole chopped in the ice. The discharge measurements are secured by the velocity determinations at holes cut in the ice at points in the cross section. Soundings are referred to the surface of the water in the holes. Velocity measurements are made at 0.2 and 0.8 of the total depth (below the bottom of the ice), the mean velocities at these two points being very nearly in the mean velocity of the vertical.

The results of stream measurements during the frozen season are given for a number of streams in the northeastern United States, the period covering several years. The vertical velocity curves from the results of these measurements show, as is to be expected, a greater drawing back of the curve in its upper portion on account of the retarding effect of the ice than do curves in which the friction effect at the upper surface is merely that of the air.

Progressiveness in Italy, H. C. WEEKS (*Sci. Amer. Supp.*, 63 (1907), No. 1637, pp. 26233-26235, figs. 3).—The article describes in some detail the con-

struction of a large drainage canal in Italy known as the Bonifica dell' Agro Mantovano-Reggiano, which drains an area of 80,000 acres south of the Po in the vicinity of Reggio. There are many points of interest in the project, notably in the use of inverted siphons, where the main channel crosses the Secchia River, in the provisions for regulating the drainage in order to retain moisture in the soil when necessary, and in the use of pumps at the outlet for discharging water into the Po at periods of high water.

Public roads: Mileage and expenditures in 1904 (*U. S. Dept. Agr., Office Pub. Roads Circs.* 53, pp. 4; 54, pp. 2; 55, pp. 2; 56, pp. 2; 57, pp. 3; 58, pp. 4; 59, pp. 3; 60, pp. 4; 61, pp. 4; 62, pp. 2; 63, pp. 4; 64, pp. 2; 65, pp. 3; 66, pp. 4; 67, pp. 3; 68, pp. 3; 69, pp. 3; 70, pp. 4; 71, pp. 3; 72, pp. 4; 73, pp. 3; 74, pp. 4; 75, pp. 4; 76, pp. 4; 77, pp. 4; 78, pp. 3; 79, pp. 3; 80, pp. 4; 81, pp. 2; 82, pp. 4; 83, pp. 2; 84, pp. 3; 85, pp. 6; 86, pp. 2; 87, pp. 2).—In this series of circulars information is compiled on the mileage of different classes of roads, the sources of revenue by which they are supported, and the road expenditures in cash and labor by counties in each of the following States: Pennsylvania, Montana, Wyoming, North Dakota, South Dakota, Kentucky, Florida, South Carolina, Nevada, Kansas, Idaho, Colorado, Indiana, Oklahoma, Utah, California, Illinois, New Jersey, Missouri, Louisiana, New York, Ohio, Georgia, Mississippi, West Virginia, Wisconsin, Minnesota, Delaware, Michigan, Rhode Island, Massachusetts, Texas, Connecticut, and Vermont.

RURAL ECONOMICS.

On the proportion and importance of small farms in Sweden, E. SIDEN-PLADII (*K. Landtbr. Akad. Handl. och Tidskr.* 45 (1906), No. 6, pp. 409-438).—This article treats of the importance of small farms in Swedish agriculture and the various direct and indirect measures adopted by the government for the advancement of small farmers, such as the offering of prizes for well-conducted farms, the payment of traveling expenses for studies in foreign countries or in different parts of Sweden, and the securing of improvement through dairy test associations, educational institutions, etc. It is shown that 46.9 per cent of all farms in Sweden are of less than 5 hectares (12.3 acres) in extent, 22.8 per cent contain from 5 to 10 hectares, and 13 per cent are from 10 to 15 hectares. Only 2.3 per cent of the total number of farms contain more than 50 hectares. About one-fourth (25.9 per cent) of the total arable land is in farms of less than 10 hectares and very nearly one-half in farms of less than 50 hectares.—F. W. WOLL.

Report of the agricultural committee, H. CHAPLIN ET AL. (*London: Tariff Commission, 1906, pp. 555, figs. 19*).—This is the report of a special agricultural committee appointed by the tariff commission of Great Britain "to examine the proposals submitted by Mr. Chamberlain to the country and their bearing upon the agricultural interest."

The committee held 33 meetings, examined 147 witnesses, and received replies to letters of inquiry from 2,103 agriculturists and others concerned in agriculture. The report of the committee is presented under the following topics: Agricultural policy before 1846, agriculture in the nineteenth century, international conditions, recent agricultural conditions in the United Kingdom, imports of agricultural produce and their relation to the home production, experiences of farmers, and conclusions and remedial measures. On the latter point the committee says:

"We are of opinion that, for removing the disabilities under which British agriculturists suffer, a change in the fiscal policy of the country is absolutely necessary, but if this change is to be permanently effective it must be combined

with measures dealing with transport, the enlargement of the powers of the board of agriculture, and local taxation. We are also of opinion that the position of the industry generally would be improved if means could be found to create further facilities for land purchase in the United Kingdom."

An appendix contains the evidence of witnesses, the replies to letters of inquiry, and memoranda on the possibilities of sugar manufacture in the United Kingdom, sugar beet and tobacco cultivation in the United Kingdom, and the purchase of land bill for England and Wales.

Share system in cane cultivation in Fiji, Hawaii, and Mauritius. H. M. JACKSON (*West Indian Bul.*, 6 (1905), No. 1, pp. 18-21; 7 (1906), No. 4, pp. 311-316).—The share system consists in the division of the land to be cultivated into blocks of about 60 acres, the owners doing the preliminary work of preparing the land and planting it before handing it over to the cooperative company of laborers who do the balance of the work until the cane is fit for cutting. The owners also advance to the workers one shilling a day each for maintenance with which they are duly debited. The cane is sold to the factories, and the proceeds, after deducting the landowner's share and all expenses of cultivating, harvesting, carting, etc., are divided pro rata among the laborers.

The advantages of the system are a lessening of the annual heavy expense of introducing a new supply of laborers, more efficient service on the part of the field hands, higher wages for service, and the retention of the farm help on the land. This latter effect is regarded as affording a solution of the farm-help problem in these countries.

Report of the commission on contract labor. P. FAYRE (*Bul. Soc. Vaudo. Agr. et Vit.*, 1907, No. 203, pp. 407-414).—This is a report presented to the assembly of delegates of the agricultural and viticultural society of the Canton of Vaud at Lausanne in December, 1905.

The questions sought to be answered were: Why contracts between farmers and hired help were not respected by the latter, and what remedy could be suggested? As answer to the first question the committee names two causes. The great scarcity of farm help is assigned as the chief cause, the laborer knowing that if he leaves one employer he can readily find another place at possibly an increase of wages. The causes assigned for the scarcity of reliable farm laborers are the system of education in Vaud, insufficient remuneration for farm labor, too many hours for a day's labor—14 to 16 daily and little less on Sundays—and the various social industries which offer steady employment and other advantages which draw men from the farm to the towns and the cities. The absence of a law controlling the relations between master and hired man is given as the second cause why contracts are not better respected by hired farm laborers.

As a remedy the commission recommends the passage of a suitable national law which should aim to safeguard the rights of the master in matters pertaining to the hiring of laborers.

Statistics of agricultural associations for 1905 (*Bul. Agr. [Brussels]*, 23 (1907), No. 3, pp. 215-280).—Detailed statistics of agricultural organizations in Belgium for 1905 in comparison with preceding years are reported.

The statistics relate primarily to the number of societies in each province, the membership, and the business transacted, and include the following general groups: Federations of professional agriculturists; cooperative societies for the purchase of seeds, commercial fertilizers and feeding stuffs, and farm machinery; cooperative societies for the manufacture and sale of dairy products; agricultural credit organizations, and agricultural insurance societies, which include the insurance of live stock and crops destroyed by hail.

The agricultural population and the farm-help problem in England, B. SKALWEIT (*Mitt. Deut. Landw. Gesell.*, 22 (1907), *Beilage* No. 6, pp. 27-34).—Statistical data are presented regarding the number of the rural population and different groups of farmers and farm laborers in the United Kingdom for the years 1851 to 1901, with a discussion of the effect of recent legislation and the price of wheat on the English agricultural labor problem.

The statistics show that while the population in the United Kingdom increased about 10 millions from 1870 to 1900 the rural population decreased about 4 millions, and that farmers and farm laborers, including males and females, decreased from 3,454,000 in 1851 to 2,262,000 in 1901. The tendency of recent legislation has been to increase rural settlement. A number of bibliographical references are included.

Cooperation in agriculture [in Denmark] (*Danmarks Statist. Meddel.*, 4, ser., 22 (1907), pt. 5, pp. 69).—Statistical data with a discussion regarding the development of agricultural cooperation in Denmark along the lines of dairying, registration of most productive cows, slaughterhouses, and exportation of eggs.

The data show the number of cooperative dairies in 1906 to have been 1,068, with a membership of about 157,500. Registry societies, which record food consumption as well as milk production as the basis of determining the most productive cows, numbered 415 in 1905, with a membership in 1903 of 8,504, controlling 148,000 cows. There were 32 cooperative slaughterhouses in 1905 with 70,000 participants and 790 cooperative egg unions in 1906 with 57,000 members.

An agricultural credit system for Cape Colony (*Agr. Jour. Cape Good Hope*, 30 (1907), No. 2, pp. 186-192).—This is a review of a pamphlet issued by the treasury department in regard to proposed legislation for improving the credit of agriculturists in the colony.

The pamphlet reviews the conditions of agriculture, the lack of capital, the burden of high interest, and the importance of encouraging the development of agriculture in Cape Colony. The proposal is made to adopt a system of government credit and supervision largely conformable to the Australian and New Zealand system (*E. S. R.*, 18, p. 687), with slight modifications as to amounts and classes of loans, payment of costs, length of period during which loans may run, and on management and control of the funds.

The granger movement in Illinois, A. E. PAINE (*Univ. Ill. Bul.*, 2 (1904), No. 2, pp. 53).—The author briefly reviews the origin, aims, and history of the organization known as the Patrons of Husbandry among farmers in the United States, with a detailed account of its progress in Illinois.

The greatest activity was manifested in 1873 and 1874, during which 1,465 granges were organized. This was followed by a decline for a number of years. Since 1880, however, "there has been a revival, and the grange, with a gradually increasing membership, has been able to pursue a well-defined policy, emphasizing the need of education and the necessity for self-improvement. . . . There need be no hesitation in affirming that no small share of the political, social, and industrial progress of the farmer in Illinois may be traced to the grange." An extensive bibliography is included.

Crop Reporter (*U. S. Dept. Agr., Bur. Statist. Crop Reporter*, 9 (1907), No. 6, pp. 41-48).—Statistics and notes on the condition of crops, and the supplies, value, and prices of agricultural products in the United States and foreign countries are summarized. A special article gives statistics showing the increase in rubber production in recent years and the acreage under cultivation in various countries to meet the increased demand for this product.

Returns of produce of crops in Great Britain with summaries for the United Kingdom, R. H. REW (*Bd. Agr. and Fisheries [London], Agr. Statist.*, 1906, pt. 2, pp. 89-168).—The estimated total produce, acreage, and estimated

yield per acre for 1906 in comparison with preceding years are reported. A summary of weather statistics of Great Britain is included.

The gross production of the principal crops in the United Kingdom are given as follows: Wheat 7,577,000, barley 8,435,000, and oats 21,859,000 quarters, respectively; potatoes 6,089,000, turnips 27,583,000, mangels 9,881,000, and hay of all kinds 13,512,000 tons, respectively.

Illinois Crop Report for December 1, 1906, W. C. GARRARD (*Statist. Rpt. Ill. Bd. Agr., 1906, Dec. 1, pp. 94*).—A summary of the reports of correspondents as to the yield, value, and price of the principal farm products and the number and value of live stock of Illinois for the year 1906, in comparison with similar data for preceding years. Corn was the leading crop, being valued at \$103,489,520, followed by oats valued at \$27,462,112. The total value of the principal crops and live stock in Illinois for 1906 was \$253,409,404.

Kansas statistics, 1905-6, F. D. COBURN (*Quart. Rpt. Kans. Bd. Agr., 25 (1906), No. 100, pp. 73; Bicn. Rpt. Kans. Bd. Agr., 15 (1905-6), pp. 997-1263*).—In these reports tables are given showing the State's population by counties and cities, assessed valuation, acres, yields, and value of agricultural products, and numbers and value of live stock for the years 1905 and 1906. The total acreage of the State is 52,572,160, of which 31,562,268 acres were under culture in 1905 and 30,989,263 in 1906, the values of all farm products, including animals slaughtered, being \$238,836,425 and \$246,905,051, respectively. The live stock numbered 6,686,520 in 1905, having a value of \$169,821,157, the corresponding figures for 1906 being 6,419,742 and \$177,429,816. Corn and wheat were the leading products of the State.

Official report on the condition of crops and wages of farm hands (*Ohio Dept. Agr., 1907, pp. 13*).—The condition of crops in Ohio on April 1, 1907, compared favorably with that at the same time last year. Live stock wintered well and were in fine condition. The average wages of farm hands were \$21 per month with board, \$29 without board, \$1.10 per day with board, and \$1.40 without board.

"The labor problem is still a serious one for farmers, and although wages have materially advanced over last year, farmers are unable to secure sufficient help to properly carry on farming operations. In those localities situated in close proximity to cities it is almost impossible to secure reliable farm help."

Prices of agricultural and other products in Serbia (*Statistique des Prix des Produits Agricoles et Autres dans la Royaume de Serbie. Belgrade: Gort., 1906, pp. LVII+429, dgms. 4*).—Detailed statistics of the prices of agricultural products for each month of the years 1901 to 1905, inclusive, are reported.

Danish agriculture in 1906, H. HERTEL (*Tidsskr. Landökonomi., 1907, No. 1, pp. 1-40*).—A general review of agricultural conditions during the year.

Imports of agricultural produce in 1906 (*Jour. Bd. Agr. [London], 13 (1907), No. 10, pp. 615-621*).—Statistics relating to the source, quantity, and value of agricultural products imported into the United Kingdom in 1905 and 1906 are reported and discussed. The total value of all farm imports in 1906, the bulk of which were food supplies, amounted to £246,940,000. The general tendency of prices for all imported farm products was higher in 1906 than in the preceding year. Argentina again surpassed the United States in the quantity of refrigerated meat supplied to Great Britain, but the price of American meat was more than 50 per cent higher than the Argentine product.

[Agricultural statistics of Uruguay for 1905-6], A. ARECHAVALETA (*Montevideo: Gort., 1906, pp. 32*).—This report gives statistics and discusses the number of hectares under cultivation and yields of wheat, corn, flax, oats, barley, and canary seed; the number of farm laborers; the number of farms in operation by native and foreign owners or renters, and the number of work animals and

implements, with detailed information regarding the 449 threshing machines owned in Uruguay. There were 22,593 farmers in 1906, of which 10,807 owned and 11,786 rented the farms worked; 13,219 were natives and 9,374 foreigners.

Season and crop report of the Bombay Presidency [and Sind] for the year 1905-6, P. J. MEAD (*Season and Crop Rpt. Bombay, 1905-6*, pp. VI+68).—In addition to statistics on rainfall this report discusses the agricultural conditions of the presidency and the district of Sind for the year 1905-6.

The total area under crops and in fallow was 39,097,000 acres, of which 20,730,000 acres were in food crops and 5,911,000 acres in nonfood crops. The live stock numbered 13,849,000, and the cotton production was 1,232,000 bales. On account of deficiency in rainfall crops were below the normal and prices were generally high. Detailed statistical data are also presented on the number of acres in cereals and pulse, irrigation, sources of water supply, and the number of acres of uncultivated land.

AGRICULTURAL EDUCATION.

Statistics of agricultural institutions in Prussia for 1903-1905 (*Landw. Jahrb.*, 35 (1906), Sup. 5, pp. XXII+485).—This report contains detailed statements concerning the organization, faculty, income, courses of study, attendance, etc., of the agricultural institutions of different grades in Prussia. These include (1) agricultural, forestry, and veterinary schools known as academies, (2) secondary agricultural schools (Mittelschulen), (3) elementary agricultural schools (niedere Schulen), (4) special schools, such as schools of pomology, horticulture, fruit growing, meadow culture, dairying, etc., (5) special courses for adults, and (6) normal schools for the training of teachers of agriculture. A tabular review is also given of the progress and present status of rural continuation schools. Twenty appendixes contain rules and decrees concerning the qualifications of teachers, examinations, the inspection service, and other matters relating to the institutions listed in the report.

Agricultural education in England and Wales (*Jour. Bd. Agr. [London]*, 13 (1907), No. 11, pp. 641-660, map 1).—This is a very satisfactory brief summary of the educational institutions of different grades in England and Wales which afford instruction in agriculture. An outline of the different lines of instruction is first given, including courses for degrees in agriculture, diploma courses, short courses, and the special instruction in dairying, horticulture, poultry keeping, and forestry. Then follows a description of the different institutions engaged in this work, the courses offered by each, the tuition fees and other expenses, their land, buildings, and other equipment, and in some cases other details.

Normal training in high schools (*Advance pages from the Bich. Rpt. State Supt. [Pub. Instr.] Nebr. [1907]*, pp. 99-102).—This embodies an account of the steps taken to inaugurate normal training courses in the high schools of Nebraska after September 1, 1907, in accordance with the law enacted by the State legislature in 1905.

A committee of the State Association of Superintendents and Principals of Accredited High Schools, appointed to formulate general requirements for normal training courses in high schools, decided that a high school, in order to be approved for a normal training course, must be accredited by the University of Nebraska, must have at least 3 teachers, normal training credits to be open only to high school graduates, the course to include a review in the common branches for at least 9 weeks not earlier than the eleventh grade, a study of American history for at least 1 semester in the eleventh or twelfth grade, and at least 72 periods of professional training in the twelfth grade. Schools offering this

course must have a reference library on professional subjects and must teach elementary agriculture. Outlines are given to show the plan and scope of the work in the common branches and the professional training, including agriculture.

The work in agriculture is intended to cover 2 semesters or 1 year. The work of the first semester includes farm animals, class work 32 periods and laboratory work 8 double periods; milk and its products, 20 periods and 5 periods, respectively; and soils, 12 periods and 3 periods, respectively. In the second semester 12 class periods and 8 double laboratory periods are devoted to soils, 18 class periods and 12 double laboratory periods to field crops, and 18 class periods and 12 double laboratory periods to orchard and garden crops. The subjects for the different laboratory exercises are given, and also lists of equipment needed for laboratory work and of reference books for the library.

For schools not equipped to carry the 2-semester course a briefer 1-semester course is outlined.

Outlines in agriculture for Nebraska State junior normal schools (*Lincoln: Dept. Pub. Instr., 1906, pp. 55, figs. 5*).—These are outlines prepared by the instructors in agriculture in the Nebraska State junior normal schools under the direction of the University of Nebraska. They include detailed suggestions for the study of field crops (cereals and forage crops), soils, and horticulture. Nineteen experiments in soils are described. Under the subject of horticulture the following topics are treated: Selection of site for gardens and orchards, propagation, transplanting, pruning and training, treatment of insects and diseases, school grounds, tillage of gardens and orchards, and the school garden. There is also a syllabus for the study of farm animals.

The home economics movement, I, ISABEL BEVIER and SUSANNAH USHER (*Boston: Whitcomb & Barrows, 1906, pp. 67*).—This is a brief historical account of the development of education for women in the United States, the origin of instruction in home economics in agricultural colleges and State universities, the development of special cooking schools, and the origin and development of home economics in public schools.

Agriculture in public schools, W. C. LATTI (*Nature-Study Rev., 3 (1907), No. 2, pp. 43-49*).—This is a discussion of what should be included in the course in agriculture for public schools, why agriculture should be taught in public schools, and how it should be introduced. Among the things to be included are the phenomena and forces of nature, considering first the most familiar and later those less known, the relations of cause and effect, the effect of environment on the life of the child, on all life, and on the practice and products of the farm, and the story of nature as a whole so far as it comes within the scope of the child's mind and affects him.

Nature studies on the farm. Soils and plants, C. A. KEFFER (*New York, Cincinnati, and Chicago: American Book Co., 1907, pp. 154, figs. 59*).—This is a series of reading lessons for children dealing in a simple and popular way with soils and their relation to plant life, the relation of the forest to the soil, weeds, "the plant's business," buds and seeds, sowing the seed, rotations, cultivation, the hoed crops, cereals and grasses, hotbeds, cuttings, transplanting, the garden, the orchard, and other subjects of the country home. The last few pages of the book are devoted to suggestions to teachers, including some information concerning each lesson, and suggestions for exercises to be conducted in connection with the readings.

Practical suggestions for improving and beautifying rural school grounds, T. H. SCHEFFER (*Industrialist, 33 (1907), No. 15, pp. 227-235, dgm. 1*).—This article gives specific suggestions concerning many matters related to the planning, planting, and using of grounds surrounding rural schools. The topics considered are the selection of a site, size of grounds, the plan and location of

buildings, the walks and driveways, fences, grading, playgrounds, and lawn, the location of trees and shrubs, the kinds of trees and shrubs to plant, how to plant them, the care of trees, the use of flowers, and the district policy with reference to the manner of getting the work done.

Arbor Day (*U. S. Dept. Agr., Forest Serv. Circ. 96, pp. 4*).—This circular comprises brief suggestions concerning the lesson of the day, nature study and forestry, forest topics to group about Arbor Day, and planting.

MISCELLANEOUS.

Seventeenth Annual Report of Arizona Station, 1906 (*Arizona Sta. Rpt. 1906, pp. 127-166*).—This consists of an administrative report on the work of the station as a whole and four departmental reports. These reports contain, among other things, notes on the culture of date palms, olives, cassava, taniers, taros, avocados, and tobacco; the results of feeding experiments with sheep; notes on alfalfa root rot, and a financial statement for the fiscal year ended June 30, 1906.

Nineteenth Annual Report of Rhode Island Station, 1906 (*Rhode Island Sta. Rpt. 1906, pp. 159-341+VII*).—This contains the organization list of the station, a report of the director reviewing briefly the work of the station during the year, departmental reports abstracted elsewhere, a financial statement for the fiscal year ended June 30, 1906, exchanges, etc.

Circulars, finances, meteorology, index (*Maine Sta. Bul. 137, pp. 283-314+VIII*).—This bulletin consists of reprints of press bulletins issued during the year, meteorological observations noted elsewhere, a financial statement for the fiscal year ended June 30, 1906, an index to Bulletins 125-137 which collectively make up the twenty-second annual report of the station, and notes on the work and history of the station. The subjects of the newspaper bulletins and circulars are as follows: Potato scab; white grubs and June beetles; red-humped caterpillar; the yellow-edge or mourning-cloak butterfly; elm leaf-curl; yellow-necked caterpillar; the cecropia moth; tent caterpillar; and tussock moths.

Twenty-second Annual Report of the Bureau of Animal Industry, 1905 (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1905, pp. 364*).—This includes a report of the chief of the Bureau for the fiscal year ended June 30, 1905, numerous articles abstracted elsewhere in this issue, a list of the publications of the Bureau during 1905, and the rules and regulations of the Bureau issued in 1905.

Publications of the Bureau of Animal Industry (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 106, pp. 24*).—A complete list of the publications of this Bureau to April 1, 1907.

NOTES.

Alaska Stations.—A breeding station has recently been established at Kodiak as a fourth substation. Experiments in cattle raising are to receive special attention, but hardy breeds of sheep and possibly Shetland ponies may be added. Work has been inaugurated with a herd of Galloways, this breed being selected because of its hardiness, its ability to "rustle," and its heavy coat, all of which qualities adapt it to Alaska conditions. In its initial stage the chief object will be to ascertain whether cattle can be bred successfully in Alaska, and if so how they should be managed, how best to produce the necessary feed, and related questions. A secondary purpose is to produce a general-purpose cow from the Galloway, since dairy products are needed in Alaska as well as beef, and none of the distinctive dairy breeds are adapted to the climate. It is planned to offer the surplus stock for sale to settlers.

Florida University and Station.—E. L. Wartman, of Citra, Fla., has been appointed on the board of control, vice A. L. Brown, whose commission expired. The last legislature, which adjourned June 1, appropriated \$570,711 for higher education during the next biennium. The State board of education, which has general supervision and allotment of this fund, has decided to allot \$150,000 to the university for buildings, \$40,000 of which is to be used for the construction of laboratories and offices for the station. For the ensuing biennium \$10,000 has been set aside for farmers' institutes and \$5,000 for farm buildings and improvements on the station grounds. John Belling has been elected assistant in horticulture.

Kentucky College and Station.—B. R. Hart, assistant chemist in charge of feed analysis in the station, and W. G. Campbell, formerly of the station, have accepted positions with the Bureau of Chemistry of this Department, in connection with the food inspection work. H. D. Spears, assistant in chemistry in the college, has been placed in charge of the feed work of the station.

Maine Station.—Frank M. Surface, Ph. D., a recent graduate of the University of Pennsylvania, has been appointed associate biologist in the station, and will be engaged in collaboration with Doctor Pearl in investigations in plant and animal breeding. After taking his degree Doctor Surface was elected to a Harrison research fellowship in zoology at the University of Pennsylvania, which he resigned to accept the position at the station.

Michigan Station.—F. A. Spragg, a graduate of the Montana College, has been appointed assistant agronomist, and will have charge of the breeding work with cereals, legumes, and farm crops. A new insectary is to be constructed at once as an annex to the agricultural laboratory. Plans have been submitted for a new agricultural building to cost \$150,000.

Nebraska University and Station.—According to a note in *Science*, F. G. Miller, in charge of forestry work, has resigned to accept a similar position in the newly established forestry school of the University of Washington. He will be succeeded by F. J. Phillips of the Forest Service of this Department.

New Hampshire Station.—Jasper F. Eastman, a recent graduate of the Massachusetts College, has been appointed assistant in agriculture. T. J. Headlee, assistant entomologist, has resigned to become entomologist at the Kansas College and station.

Cornell University and Station.—B. M. Duggar, of the University of Missouri, has been elected to the professorship of plant physiology in its relations with agriculture. It is expected that he will assume his duties next February. J. B. Norton, formerly of this Department, has become assistant in the department of plant biology. The new appropriation for the college of agriculture carries \$150,000 for maintenance, \$50,000 for equipment, and \$25,000 for building barns, a total of \$225,000 for the year.

North Dakota College.—A summer school of traction engineering was held at the college July 2 to 26 under Prof. P. S. Rose, of the engineering department. The forenoon of each day was devoted to lectures on traction engineering and the economics of thrashing. In the afternoon there were lectures on gas engineering and classes in arithmetic. The practical work consisted in running both steam and gasoline traction engines, setting valves, putting in boiler tubes, babbitting boxes, lacing belts, etc., all under the direct supervision of experts in those lines of work. Each student was given time enough at practice work to become thoroughly proficient in handling and adjusting traction engines. Considerable attention was also given to the handling of grain separators.

Ohio Station.—H. S. Woods has been appointed assistant in animal nutrition. C. H. Kyle, assistant agronomist, has resigned to accept a position in the Bureau of Plant Industry, and F. A. Welton, assistant chemist, has been transferred to his position. Gail T. Abbott has been appointed second assistant in agronomy. J. S. Houser, assistant entomologist, has resigned to become entomologist of the Cuban Experiment Station.

Oregon College and Station.—At the last meeting of the board, professorships were established in agronomy, poultry husbandry, animal husbandry, and veterinary science. Dr. James Withycombe will have charge of the work in the last two lines.

Pennsylvania College and Station.—Thomas F. Hunt, dean and director, and Alva Agee, professor of agricultural extension, assumed their duties July 1. Dr. H. P. Armsby remains with the college as director of the institute of animal nutrition. The department of agriculture has been divided into departments of agronomy and animal husbandry. J. W. Gilmore, assistant professor of agronomy at Cornell University, has been elected professor of agronomy; and J. H. Barron assistant in experimental agronomy. Bailey E. Brown, of the Bureau of Soils, has, as previously noted, been assigned to the experiment station under the title of assistant professor of agronomy, and with the assistance of J. J. Skinner, also of the Bureau of Soils, is engaged in the study of the fertilizer plats which have been under experiment during the past twenty-five years. Provision has also been made for an instructor in agronomy, with special reference to soils. T. I. Mairs has been placed in charge of the department of animal husbandry and provision made for an assistant in animal husbandry and an instructor in poultry husbandry. C. L. Goodling, a graduate of the college, has been elected assistant in animal husbandry, and an assistant professor of dairy husbandry, with special reference to the manufacture of cheese, will be appointed. J. P. Stewart, as previously noted, has been elected assistant professor of experimental horticulture and has begun investigations in that subject. The position of assistant professor of botany with special reference to plant pathology, including both college and station work, has been established. The chair of agricultural chemistry has been divided. Dr. William Frear will continue as vice-director of the station and professor of experimental agricultural chemistry, and M. S. McDowell has been promoted to be assistant professor of experimental chemistry.

The legislature passed a deficiency bill for the college amounting to \$179,530.92, which included \$85,000 for the completion of the new agricultural building. The contract for finishing the new building has been let. The total appropriations for the agricultural and dairy buildings, including the heating tunnel, have been \$284,169.60. The general appropriation bill for the college carried \$274,000. A special item of \$70,000 was included in the bill for the school of agriculture and \$4,000 for experiments on tobacco by the station.

Rhode Island Station.—E. A. Mallette, who has been in the employ of the horticultural department for a few months, has been appointed a member of the station staff.

South Dakota Station.—A department of dairy industry has been added to the station. W. A. Wheeler, for the past two years botanist and entomologist in the station, has resigned, and is succeeded by Edgar W. Olive, Ph. D., of the University of Wisconsin. Doctor Olive will have charge of the botanical work and an assistant will be provided to take charge of the entomological work.

West Virginia University.—T. C. Johnson, instructor in horticulture and botany in the college of agriculture, has been made assistant professor of these subjects, and D. W. Working, of Denver, Colo., and formerly on the editorial staff of *American Grange Bulletin*, has been appointed superintendent of agricultural extension teaching. The establishment of a department of highway construction in the college of agriculture has been authorized.

Macdonald Agricultural College.—A provisional announcement of this institution, which is to open this fall, has been issued by the principal, Dr. J. W. Robertson. Three departments have been organized—a school for teachers, a school of agriculture, and a school of household science. The requirements for admission to the school for teachers are similar to those which have been in force at the McGill Normal School. Other teachers will be admitted under certain regulations for courses in nature study, school gardening, household science, and manual training. Candidates for admission to the school of agriculture must have worked for a season on a Canadian farm. No entrance examination is required of short-course students, but all candidates for the one and two year courses in agriculture and household science will be required to pass an examination in the elementary branches.

Secondary Education in Canada.—The experiment of introducing agriculture into some of the high schools of Canada is about to be tried. It is proposed to make a grant to each high school that will establish a class in agriculture and agree to appoint a teacher recommended by the department of agriculture. A plot of ground for demonstration or experimental purposes must be provided, the classes specializing according to the agricultural needs and conditions of the districts in which the schools are located. The teachers' time is to be devoted exclusively to agricultural work, but any time not required by their respective schools is to be available for assisting and encouraging agriculture and nature study in rural schools and in sending the department of agriculture information regarding pests, new and interesting developments in connection with farming, etc.

Agricultural and Industrial School for Korea.—J. Arthur Thompson, a graduate of the College of Agriculture of the University of Illinois, is on his way to Korea to assist in the establishment of an agricultural and industrial school. He is being sent by the Methodist Conference, and spent a year at Hampton Normal and Agricultural Institute preparing for the work. The people of Korea have raised \$1,000 to establish the school, and the land has been purchased. On his arrival at Songdo, Korea, Mr. Thompson will begin his new

work at once, assisted by Mr. T. H. Yun, a native Korean educated in the United States.

Avondale Forestry Station.—The Journal of the Department of Agriculture and Technical Instruction for Ireland gives an account of the establishment, object, and work of the Avondale Forestry Station and Forestry School. The station grounds comprise about 550 acres, including about 100 forest plats of an acre each for the study of trees grown under silvicultural methods in distinction from arboricultural conditions, a pinetum containing about 100 species, and an arboretum with about 150 species of 40 genera. The forestry school associated with the station was opened in the autumn of 1904 for the purpose of training working foresters and woodmen. A syllabus is given of the lectures for its four-years' course.

A New Cereal Culture Station in Italy.—By an act of June 20 there was established at Rieti an experiment station for the culture of cereals, with the object of improving and increasing the production of wheat and other cereals by means of laboratory and field experiments.

Investigation of Spike Disease.—According to *Indian Forester*, the Maharaja of Mysore has announced a reward of 10,000 rupees to anyone who will discover the cause of spike disease among sandal trees and suggest a thorough and effective and, at the same time, a cheap and easily applicable remedy for its eradication. The offer will remain open for three years. Each applicant must forward a report of his investigations, accompanied by microscopic slides, to the secretary of the general and revenue departments, Mysore. The conditions are that the cause of the disease must be definitely and clearly determined, and an effective and cheap remedy prescribed, such as would perceptibly check the spread of the disease within a year. Persons desirous of investigating this subject may obtain from the conservator of forests in Mysore copies of a printed compilation of the more important papers bearing on the subject of the eradication of this disease.

Miscellaneous.—The Agricultural and Mechanical College for the Colored Race, at Greensboro, N. C., has added a dairy department and a teachers' training department to prepare teachers especially for instruction in agricultural and mechanical branches. The college session has been increased by one month and a preparatory course is to be offered.

The Horticultural College, Swanley, England, has arranged a one-year course in natural history for students who have passed through the ordinary training in gardening and desire additional training in natural-history subjects in order to qualify as teachers of gardening and nature study. The work will be practical, the first two terms of the course to be devoted to general work in botany, zoology, and geology, and the third term to special subjects.

It is announced that the next meeting of the American Association of Farmers' Institute Workers will be held at Washington, October 23 to 25.

E. D. Merrill, botanist of the bureau of science in the Philippine Islands and a former employee of this Department, who has been in the islands for the past five years, has returned to this country on leave.

1907

U. S. DEPARTMENT OF AGRICULTURE.

Scientific Bureaus and Divisions.

WEATHER BUREAU—Willis L. Moore, *Chief*.
BUREAU OF ANIMAL INDUSTRY—A. D. Melvin, *Chief*.
BUREAU OF PLANT INDUSTRY—B. T. Galloway, *Chief*.
FOREST SERVICE—Gifford Pinchot, *Forester*.
BUREAU OF SOILS—Milton Whitney, *Chief*.
BUREAU OF CHEMISTRY—H. W. Wiley, *Chemist*.
BUREAU OF STATISTICS—V. H. Olmsted, *Statistician*.
BUREAU OF ENTOMOLOGY—L. O. Howard, *Entomologist*.
BUREAU OF BIOLOGICAL SURVEY—C. Hart Merriam, *Chief*.
OFFICE OF PUBLIC ROADS—L. W. Page, *Director*.

OFFICE OF EXPERIMENT STATIONS—A. C. True, *Director*.

THE AGRICULTURAL EXPERIMENT STATIONS.

ALABAMA—

College Station: *Aburn*; J. F. Duggar, *a*
Canebrake Station: *Uniontown*; J. M. Richeson, *b*
Tuskegee Station: *Tuskegee*; G. W. Carver, *a*

ALASKA—*Sitka*: C. C. Georgeson, *c*

ARIZONA—*Tucson*: R. H. Forbes, *a*
ARKANSAS—*Fayetteville*: W. G. Vincenheller, *a*
CALIFORNIA—*Berkeley*: E. J. Wickson, *d*
COLORADO—*Fort Collins*: L. G. Carpenter, *a*

CONNECTICUT—

State Station: *New Haven*; E. H. Jenkins, *a*
Storrs Station: *Storrs*; L. A. Clinton, *a*

DELAWARE—*Newark*: H. Hayward, *a*

FLORIDA—*Gainesville*: P. H. Rolfs, *a*
GEORGIA—*Experiment*: Martin V. Calvin, *a*

HAWAII—

Federal Station: *Honolulu*; J. G. Smith, *c*
Sugar Planters' Station: *Honolulu*; C. F. Eckart, *a*

IDAHO—*Moscow*: H. T. French, *a*

ILLINOIS—*Urbana*: E. Davenport, *a*

INDIANA—*Lafayette*: A. Goss, *a*

IOWA—*Ames*: C. F. Curtiss, *a*

KANSAS—*Manhattan*: C. W. Burkett, *a*

KENTUCKY—*Lexington*: M. A. Scovell, *a*

LOUISIANA—

State Station: *Baton Rouge*;
Sugar Station: *Audubon Park*,
New Orleans;
North La. Station: *Calhoun*;
W. R. Dodson, *a*

MAINE—*Orono*: C. D. Woods, *a*

MARYLAND—*College Park*: H. J. Patterson, *a*

MASSACHUSETTS—*Amherst*: W. P. Brooks, *a*

MICHIGAN—*Agricultural College*: C. D. Smith, *a*

MINNESOTA—*St. Anthony Park, St. Paul*: W. M. Liggett, *a*

MISSISSIPPI—*Agricultural College*: W. L. Hutchin-
son, *a*

MISSOURI—

College Station: *Columbia*; H. J. Waters, *a*

Fruit Station: *Mountain Grove*; Paul Evans, *a*

MONTANA—*Bozeman*: F. B. Linfield, *a*

NEBRASKA—*Lincoln*: E. A. Burnett, *a*

NEVADA—*Reno*: J. E. Stubbs, *a*

NEW HAMPSHIRE—*Durham*: W. D. Gibbs, *a*

NEW JERSEY—*New Brunswick*: E. B. Voorhees, *a*

NEW MEXICO—*Agricultural College*: Luther Fos-
ter, *a*

NEW YORK—

State Station: *Geneva*; W. H. Jordan, *a*

Cornell Station: *Ithaca*; L. H. Bailey, *a*

NORTH CAROLINA—*Raleigh*: B. W. Kilgore, *a*

NORTH DAKOTA—*Agricultural College*: J. H.
Worst, *a*

OHIO—*Wooster*: C. E. Thorne, *a*

OKLAHOMA—*Stillwater*: W. L. English, *a*

OREGON—*Corvallis*: J. Withycombe, *a*

PENNSYLVANIA—*State College*: H. P. Armsby, *a*

Puerto Rico—*Majaguez*: D. W. May, *c*

RHODE ISLAND—*Kingston*: H. J. Wheeler, *a*

SOUTH CAROLINA—*Clemson College*: J. N. Harper, *d*

SOUTH DAKOTA—*Brookings*: J. W. Wilson, *a*

TENNESSEE—*Knoxville*: H. A. Morgan, *a*

TEXAS—*College Station*: J. W. Carson, *d*

UTAH—*Logan*: P. A. Yoder, *a*

VERMONT—*Burlington*: J. L. Hills, *a*

VIRGINIA—*Blacksburg*: A. M. Soule, *a*

WASHINGTON—*Pullman*: E. A. Bryan, *a*

WEST VIRGINIA—*Morgantown*: J. H. Stewart, *a*

WISCONSIN—*Madison*: W. A. Henry, *a*

WYOMING—*Laramie*: B. C. Buffum, *a*

a Director. *b* Assistant director. *c* Special agent in charge. *d* Acting director.

BULLETINS OF THE OFFICE OF EXPERIMENT STATIONS.

Experiment Station Record, Vols. I-XVII, with indexes; Vol. XVIII, Nos. 1-6.

Bulletins.—No. 1, Organization and History of the Stations; No. 2, Digest of Reports of the Stations for 1883; No. 3, Meeting of Horticulturists, 1889; No. 4, List of Station Horticulturists; Nos. 5, 12, 13, 19, 23, 27, 39, 47, 59, 74, 88, 111, 122, 137, 151, and 161, Organization Lists of Stations and Colleges, 1890, 1892, 1893, 1894, 1895, 1896, 1897, 1898, 1899, 1900, 1901, 1902, 1903, 1904, 1905, and 1906; No. 6, List of Station Botanists; Nos. 7, 16, 20, 24, 30, 41, 49, 65, 76, 99, 116, 123, 142, 153, and 164, Proceedings of Association of Colleges and Stations, 1891, 1892, 1893, 1894, 1895, 1896, 1897, 1898, 1899, 1900, 1901, 1902, 1903, 1904, and 1905; No. 8, Lectures on Investigations at Rothamsted; No. 9, The Fermentations of Milk; No. 10, Meteorological Work for Agricultural Institutions; No. 11, A Compilation of Analyses of American Feeding Stuffs; No. 14, Convention of National League for Good Roads, 1893; No. 15, Handbook of Experiment Station Work; No. 17, Suggestions for Food Laboratories; No. 18, Assimilation of Nitrogen by Mustard; No. 21, Investigations on the Chemistry and Economy of Food; No. 22, Investigations at Rothamsted; No. 25, Dairy Bacteriology; No. 26, Experiment Stations: Their Objects and Work; No. 28, Composition of American Food Materials; No. 29, Dietary Studies at the University of Tennessee in 1895; No. 31, Dietary Studies at the University of Missouri in 1895; No. 32, Dietary Studies at Purdue University in 1895; No. 33, The Cotton Plant; No. 34, The Carbohydrates of Wheat, Maize, Flour, and Bread; No. 35, Nutrition Investigations in New Jersey in 1895 and 1896; No. 36, Notes on Irrigation in Connecticut and New Jersey; No. 37, Dietary Studies at the Maine State College in 1895; No. 38, Dietary Studies of the Negro in Alabama, 1895 and 1896; No. 40, Dietary Studies in New Mexico in 1895; No. 42, Cotton Culture in Egypt; No. 43, Losses in Boiling Vegetables, and the Composition and Digestibility of Potatoes and Eggs; No. 44, Metabolism of Nitrogen and Carbon; No. 45, A Digest of Metabolism Experiments; Nos. 46 and 116, Dietary Studies in New York City in 1895, 1896, and 1897; Nos. 48, 62, 82, and 94, Reports to Congress on Agriculture in Alaska; Nos. 50, 61, 83, and 93, Reports on the Work and Expenditures of the Agricultural Experiment Stations, 1897, 1898, 1899, and 1900; Nos. 51, 64, 78, 97, 114, and 128, Statistics of the Colleges and Stations, 1897, 1898, 1899, 1900, 1901, and 1902; No. 52, Nutrition Investigations in Pittsburg, Pa., 1894-1896; No. 53, Nutrition Investigations at the University of Tennessee in 1896 and 1897; No. 54, Nutrition Investigations in New Mexico in 1897; No. 55, Dietary Studies in Chicago in 1895 and 1896; No. 56, Instruction in Cooking in the Public Schools of New York City; No. 57, Varieties of Corn; No. 58, Water Rights on the Missouri River and its Tributaries; No. 60, Laws for Acquiring Titles to Water from the Missouri River and its Tributaries; No. 63, Description of a New Respiration Calorimeter and Experiments on the Conservation of Energy; No. 66, The Physiological Effect of Creatin and Creatinin; No. 67, Studies on Bread and Bread Making; No. 68, Some Chinese Vegetable Food Materials and their Value; No. 69, Experiments on the Metabolism of Matter and Energy; No. 70, Water-Right Problems of Bear River; No. 71, Dietary Studies of Negroes in Eastern Virginia in 1897 and 1898; No. 72, Farmers' Reading Courses; No. 73, Irrigation in the Rocky Mountain States; No. 75, Dietary Studies of University Boat Crews; No. 77, The Digestibility of American Feeding Stuffs; No. 79, Farmers' Institutes: History and Status; No. 80, The Experiment Stations in the United States; No. 81, Irrigation in Wyoming and its Relation to Ownership and Distribution; No. 84, Nutrition Investigations at the California Experiment Station, 1896-1898; No. 85, The Digestibility and Nutritive Value of Bread; No. 86, The Use of Water in Irrigation; No. 87, Irrigation in New Jersey; Nos. 89 and 117, Effect of Muscular Work upon the Digestibility of Food and the Metabolism of Nitrogen, Conducted at the University of Tennessee, 1897-1900; No. 90, Irrigation in Hawaii; No. 91, Nutrition Investigations at the University of Illinois, North Dakota Agricultural College, and Lake Erie College, Ohio, 1896-1900; No. 92, The Reservoir System of the Cache la Poudre Valley; No. 95, Report on the Agricultural Resources and Capabilities of Hawaii; No. 96, Irrigation Laws of the Northwest Territories; No. 98, The Effect of Muscular Work on Food Consumption, Digestion, and Metabolism of Bicyclers; No. 100, Report of Irrigation Investigations in California; No. 101, Studies on Bread and Bread Making, 1899 and 1900; No. 102, Losses in Cooking Meat, 1898-1900; No. 103, The Evolution of Reaping Machines; Nos. 104, 119, 133, and 158, Reports of Irrigation Investigations for 1900, 1901, 1902, and 1904; No. 105, Irrigation in the United States; No. 106, Investigations on the Rothamsted Soils; No. 107, Nutrition Investigations among Fruitarians and Chinese, 1899-1901; No. 108, Irrigation Practice Among Fruit Growers on the Pacific Coast; No. 109, Metabolism of Matter and Energy in the Human Body, 1898-1900; Nos. 110, 120, 138, 154, and 165, Proceedings of Farmers' Institute Workers, 1901, 1902, 1903, 1904, and 1905; No. 112, Agricultural Experiment Stations in Foreign Countries; No. 113, Irrigation of Rice in the United States; No. 118, Irrigation from Big Thompson River; No. 121, Experiments on the Metabolism of Nitrogen, Sulphur, and Phosphorus; No. 124, Report of Irrigation Investigations in Utah; No. 125, A Digest of Recent Experiments on Horse Feeding; No. 126, Studies on the Digestibility and Nutritive Value of Bread at the University of Minnesota in 1900-1902; No. 127, Instruction in Agronomy at Some Agricultural Colleges; No. 129, Dietary Studies in Boston and Springfield, Philadelphia, and Chicago; No. 130, Egyptian Irrigation; No. 131, Plans of Structures in Use on Irrigation Canals in the United States; No. 132, Further Investigations Among Fruitarians at the California Agricultural Experiment Station; No. 134, Storage of Water on Cache la Poudre and Big Thompson Rivers; No. 135, Legislation Relating to Farmers' Institutes; No. 136, Experiments on the Metabolism of Matter and Energy in the Human Body, 1900-1902; No. 139, Special and Short Courses in Agricultural Colleges; No. 140, Acquisition of Water Rights in the Arkansas Valley in Colorado; No. 141, Experiments on Losses in Cooking Meat, 1900-1903; No. 143, Studies on the Digestibility and Nutritive Value of Bread at the Maine Agricultural Experiment Station, 1899-1903; No. 144, Irrigation in Northern Italy—Part I; No. 145, Preparing Land for Irrigation and Methods of Applying Water; No. 146, Current Wheels: Their Use in Lifting Water for Irrigation; No. 147, Report on Drainage Investigations, 1903; No. 148, Report on Irrigation Investigations in Humid Sections of the United States in 1903; No. 149, Studies of the Food of Maine Lumbermen; No. 150, Dietary Studies at the Government Hospital for the Insane, Washington, D. C.; No. 152, Dietary Studies with Harvard University Students; No. 155, Agricultural Instruction for Adults in the British Empire; No. 156, Studies on the Digestibility and Nutritive Value of Bread and of Macaroni at the University of Minnesota, 1903-1905; No. 157, Water Rights on Interstate Streams: The Platte River and Tributaries; No. 159, A Digest of Japanese Investigations on the Nutrition of Man; No. 160, School Gardens: A Report upon Some Cooperative Work with the Normal Schools of Washington, with Notes on School-Garden Methods Followed in other American Cities; No. 162, Studies on the Influence of Cooking upon the Nutritive Value of Meats at the University of Illinois, 1903-4; No. 163, Agricultural Instruction for Adults in Continental Countries; No. 166, Course in Cheese Making for Movable Schools of Agriculture; No. 167, Irrigation in the North Atlantic States; No. 168, The State Engineer and his Relation to Irrigation; No. 169, Report of Agricultural Investigations in Alaska, 1905; No. 170, Report of Agricultural Investigations in Hawaii, 1905; No. 171, Report of Agricultural Investigations in Porto Rico, 1905; No. 172, Irrigation in Montana; No. 173, Corn-Harvesting Machinery; No. 174, History of Farmers' Institutes in the United States.
